ARNOLD

Sir G. Lenthal Cheatle and Max Cutler

TUMOURS of the BREAST

Their Pathology, Symptoms, Diagnosis, and Treatment

Large Imperial 8vo (12 in. × 8 in.) *viii + 596 pp., 466 Illustrations, 18 Coloured Plates.* 50/- n

"Cheatle and Cutler's beautiful volume, happily blending in a single work the features of atlas and treatise, is the product of thirty five years of study on the normal and abnormal conditions of the breast. Probably no such intensive study of the subject has hitherto been made."—BRITISH MEDICAL JOURNAL.

"The volume must indeed contain the most detailed study of diseases of the breast that has ever been published . . It is, in fact, one of those rare books, a clinical treatise inspired by a truly scientific spirit."—THE LANCET.

¶ *An illustrated 8 page prospectus may be obtained from the publishers.*

SURGICAL PATHOLOG

By **CECIL P. G. WAKELEY, F.R.C.S. (Eng.), F.R.S. (Edin.),**
Hunterian Professor, Royal College of Surgeons of England; Surgeon, King's College Hospital; and

ST. J. D. BUXTON, M.B., B.S. (Lond.), F.R.C.S. (Eng.),
Surgeon and Orthopædic Surgeon, King's College Hospital.

In preparing this volume on "Surgical Pathology," the aim has been to put forward such account of the pathological side of surgery as will help readers with their clinical work. T illustrations have been chosen with great care and expense and leave no doubt in the mind of t reader as to the conditions they are designed to represent.

BRITISH MEDICAL JOURNAL.—"As a practical, useful, and comprehensive guide to the subject, whether for studen or practitioners, this book could not be bettered. The whole plan and execution of the work is good."

LANCET.—"Beautifully and lavishly illustrated . . . should prove of real value."

AMER. JOUR. SURG.—"The best book on surgical pathology that has come to the reviewer's attention in years."

Bristol: JOHN WRIGHT & SONS Ltd. *[Illustrated Catalogue free.]* London: SIMPKIN MARSHALL Ltd.

THE FINAL REPORT
OF
THE LANCET COMMISSION ON NURSING

Under the Chairmanship of
THE EARL OF CRAWFORD AND BALCARRES, P.C., K.T., F.R.S.

Appointed in December, 1930, to inquire into the reasons for the shortage of candidates, trained and untrained, for nursing the sick in general and special hospitals throughout the country, and to offer suggestions for making the service more attractive to women suitable for this necessary work.

Royal octavo volume of 256 pages, including many Charts. Price 2/6 net, post free 2/9.

May be obtained through any bookseller or from THE LANCET LTD.

THE LABORATORY IN SURGICAL PRACTICE

By **E. C. DODDS**, M.V.O., M.D., and **LIONEL E. H. WHITBY**, C.V.O., M.D (Camb.), M.R.C.P.(Lond.), D.P.H.
Illustrated. Price 8s. 6d. net.

Contents :—General Investigations and Treatment; Blood Transfusion; Specific Therapy; Operations associated with various pathological conditions; Genito-urinary Infections; Renal Function; Investigations in Diseases of the Gastro-intestinal Tract; Biochemical Investigations of the Pancreas and Liver; The Thyroid; Exudates, Transudates, Body Fluids, Pus; Notes on various tests and on the collection of specimens for examination; Laboratory Techniques; Index.

The Lancet—"We welcome this, the first of a new series under the general editorship of Gordon Taylor, because it fills a need. Hitherto if surgeons have desired to obtain information on the numerous tests employed in their work, they have had to consult the scattered literature or large technical laboratory manuals. Here, in simple language, Prof. Dodds and Dr. Whitby have described and explained the methods of performing such tests as those of renal function, blood grouping, and basal metabolism. They have ably summed up the occasions when such tests are called for and likely to give useful information, and the significance of the results that may be obtained. The sections on cholecystography and intravenous pyelography are especially useful, and those on the uses of serums, vaccines, and the bacteriophage are very informative. We commend the book both to working surgeons and to members of laboratory staffs."

Constable's List of Books on Medicine and Surgery sent post free on application.

MANIPULATIVE SURGERY

By A. S. BLUNDELL BANKART, M.A., M.Ch. (Cantab.), F.R.C.S.

Illustrated. Price 7/6 net

The association of manipulation with "bone-setting" and other forms of unqualified practice, and the preoccupation of surgeons generally with the bigger things of surgery, have led to much misunderstanding and neglect of this valuable resource in the field of legitimate surgery. The aim of the book is to give a brief and intelligible account of some of the uses and abuses of manipulation in surgery.

Constable's List of Books on Medicine and Surgery sent post free on application.

No entrance fee to those joining within 12 months of registration.

Application form, and full particulars, from the Secretary, Victory House, Leicester Square, W.C. 2.
Telephone : GERRARD 4314.

WHY IT IS PRESCRIBED FOR GASTRIC PATIENTS

When ordinary tea is out of the question it is essential that only really good China should be drunk. The Doctor's China Tea has won the enthusiastic approval of practitioners simply because it is a perfect blend of a good China leaf **with all excess tannin eliminated.** It can therefore be prescribed for invalids and dyspeptics with safety—it has no ill after-effects.

THE DOCTOR'S CHINA TEA

HARDEN BROS. & LINDSAY, LTD.,
Dept. 136, 30-34, Mincing Lane, London, E.C.3.

Priced at 3/- and 3/8 per lb.
A super quality at 4/2 per lb.

THE FUNDUS of the HUMAN EYE

An Illustrated Atlas for the Physician.

By **ERNEST CLARKE**, C.V.O., M.D., F.R.C.S.,

Consulting Surgeon to the Central London Ophthalmic Hospital, etc.; Hon. Fellow, Downing College, Cambridge.

The advent of the luminous ophthalmoscope has now brought ophthalmoscopy within the reach of all, and this [illegible] much a part of the physician's equipment as the stethoscope. But although now it is easy to see the fundus of [illegible] interpret what is seen, and the observer wants a small, handy atlas that he can easily consult. It is hoped that this [illegible] need. Each plate is printed in natural colours on thin card, bound sep[illegible] s allowing the book to open flat at any page. Beneath each plate appears a short description of the [illegible] arged to a uniform diameter of nearly four inches throughout. Only the commonest fundus changes [illegible] of the plates has purposely been made as brief as possible.

51 Colour Plates. Size of Atlas $8\frac{3}{4}'' \times 5\frac{1}{2}''$. **18s.** net.

MEDICAL ANNUAL, 1932

A YEAR-BOOK OF TREATMENT AND PRACTITIONER'S INDEX:

A Review of the Year's Progress in Medicine and Surgery, arranged in Alphabetical Order.

THAT the MEDICAL ANNUAL *has reached its 50th issue is evidence of its unique value to the Medical Profession. The Editorial Staff, with 50 years' experience behind them, are able to provide, in the most readily accessible form, just that information which the Practitioner needs to keep him abreast of the times in his profession.*

As a Special Feature of this Jubilee Volume the Publishers are presenting a
SPECIAL SUPPLEMENT containing some

200 PORTRAITS OF PAST & PRESENT CONTRIBUTORS.

This should prove a feature of unique and historic interest to our numerous readers
all over the world.

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

Extract from the "British Medical Journal," Dec. 10th, 1927:—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . Madame Rose has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

MODERN MEDICAL TREATMENT

By **E. BELLINGHAM-SMITH,** M.D., F.R.C.P. Lond., and
ANTHONY FEILING, M.D. Cantab., F.R.C.P. Lond.

With an Introduction by **Sir HUMPHRY ROLLESTON,** Bart., G.C.V.O., K.C.B.

While doing justice to the older methods of treatment the Authors have included all the recent advances in therapeutics which they have found serviceable. In his Introduction Sir Humphry Rolleston speaks of "Modern Medical Treatment" as an "attractive" work, "most conveniently planned for the readers' benefit."

"*Should prove a valuable addition to the practitioners' library.*"—LANCET.

"*The book is admirable. It is full of practical details regarding treatment, and illustrated with numerous prescriptions which will be of great use to students and practitioners.*"—CLINICAL JOURNAL.

"*This excellent work . . .* "—BRITISH JOURNAL OF CHILDREN'S DISEASES.

Two Volumes, Demy 8vo. 1,432 pages. **30s.** net the set.

Radiology in Relation to Medical Jurisprudence

By **S. GILBERT SCOTT,** M.R.C.S., L.R.C.P., D.M.R. & E. Cantab.

Dr. Gilbert Scott's book is based upon the material that passed through his hands as Director of the Radiological Department of the London Hospital.

"*The book is well written and should be of value to the medical practitioner who has to give evidence in accident cases* "—BRITISH MEDICAL JOURNAL

"*The 24 radiographic illustrations are well chosen and excellently reproduced.*"—LANCET.

Demy 8vo. 76 pages. With 24 Radiographic Plates. **7s. 6d.** net.

Radium Therapy: Principles and Practice

By **G. E. BIRKETT,** *M.C.*, B.A. Cantab., M.R.C.S. Eng.,

Late Honorary Radiologist, Manchester and District Radium Institute and Christie Hospital for Cancer.

"*Presents concisely and attractively the position that has been reached in this branch of therapeutics.*" —LANCET.

"*The book is well and simply written, there is a good index, and the illustrations are excellent.*"—BRITISH MEDICAL JOURNAL.

Royal 8vo. 196 pages. With 6 Colour and 13 Half-tone Plates and 52 Text-figures. **17s. 6d.** net.

Sick Children: Diagnosis and Treatment

A Manual for Students and Practitioners.

By **DONALD PATERSON,** B.A. Manitoba, M.D. Edin., F.R.C.P. Lond.

"*A concise and well-illustrated volume, in which material of the utmost importance to the student and practitioner is clearly set out and admirably indexed.*"—BRITISH MEDICAL JOURNAL.

"*Deserves the very highest commendation . . . It is particularly suitable for the senior students and general practitioners for whom it is written, and it deserves a place on the shelves of all specialists on diseases in children.*"—BRITISH JOURNAL OF CHILDREN'S DISEASES.

Crown 8vo. 542 pages. With 16 Half-tone Plates and 85 Text-figures. **16s.** net

---

The Cause of Cancer

By **W. E. GYE,** M.D., and **W. J. PURDY,** M.B.,

Members of the Scientific Staff of the National Institute for Medical Research, London.

"*The fascinating record of six strenuous years of research.*"—BRITISH MEDICAL JOURNAL.

"*The book is one which every student of cancer should read and consider.*"—LANCET.

Crown 4to. 530 Pages. With 105 Diagrams. **30s.** net.

"A remarkable book. It is a record, freely annotated, of a man with a rich experience of many sides of a doctor's life . . . should prove most useful as well as entertaining."—*Lancet*.

GENERAL PRACTICE. Some Further Experiences. By ERNEST WARD, M.D., F.R.C.S., author of "Medical Adventure," &c. 3s. 6d. net; post free 4s.

"Mr. WARD has done a great service to young medical men in writing this book. The book is extremely interesting and concise . . . we strongly recommend it to all senior medical students."—*Manchester University Medical School Gazette*.

ARNOLD

By Sir JOHN COLLIE, C.M.G., M.D. **Ready April 28th.**

FRAUD IN MEDICO-LEGAL PRACTICE

xii + 276 pages. *46 Illustrations.* 10*s.* 6*d. net.*

The author's immense experience as consultant to the Ministry of Pensions and to many insurance companies and public bodies is sufficient guarantee of the value of this concise new book ; Sir John is admittedly an unrivalled authority upon this subject. The needs of the general practitioner, who only occasionally meets cases of malingering, have been borne in mind throughout.

THE DIAGNOSIS OF NERVOUS DISEASES

By **Sir JAMES PURVES-STEWART,** K.C.M.G., C.B., M.D Edin., F.R.C.P., Senior Physician, Westminster Hospital. *Seventh Edition.* viii + 748 pages. 311 Illustrations. 35s. net.

CONSTABLE

FRACTURES

By **MEURICE SINCLAIR,** C.M.G., M.B., B.Ch.(Edin.), Major R.A.M.C.(Ret.). With an Introduction by **Sir ROBERT JONES,** Bt., K.B.E., F.R.C.S., etc. Illustrated. **24s. net.**

Third Edition Revised of **MODERN METHODS OF**

FEEDING in INFANCY and CHILDHOOD

By **DONALD PATERSON,** B.A., M.D.(Edin.), F.R.C.P.(Lond.), Physician for Diseases of Children, Westminster Hospital ; Physician to Out-Patients, Hospital for Sick Children, Great Ormond Street, and **J. FOREST SMITH,** F.R.C.P.(Lond.), Physician to Out-Patients, St. Thomas's Hospital; late John and Temple Research Fellow in Diseases of Children, St. Thomas's Hospital. **7s. 6d. net.**

MANIPULATIVE SURGERY

By **A. S. BLUNDELL BANKART,** M.A., M.Ch., F.R.C.S. Illustrated. **7s. 6d. net.**

The author destroys the illusion that manipulation is a special branch or cult of surgery. He shows that when properly applied, it is one of the most valuable therapeutic measures available to medical practitioners.

THE LABORATORY in SURGICAL PRACTICE

By **E. C. DODDS,** M.V.O., M.D., and **LIONEL E. H. WHITBY,** C.V.O., M.D. Illustrated. **8s. 6d. net.**

Introduces the Practitioner to the specialised facilities now available in medical schools and hospitals.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY LIMITED

(FOUNDED 1892)

President: Sir JOHN ROSE BRADFORD, Bart., K.C.M.G., C.B., C.B.E., M.D., F.R.C.P., F.R.S.

Trustees for the Reserve Fund:
Rt. Hon. LORD DAWSON, P.C., G.C.V.O., K.C.B., M.D., P.R.C.P. Sir JOHN ROSE BRADFORD, Bart., K.C.M.G., C.B., C.B.E., M.D., F.R.C.P., F.R.S. Sir SQUIRE SPRIGGE, M.D., F.R.C.P., F.R.C.S.

The Society was founded for the following purposes: To protect, support, and safeguard the character and interests of legally qualified Medical and Dental Practitioners; to advise and assist Members of the Society in matters affecting their professional character and interests; and to indemnify them in regard to actions, etc., undertaken on their behalf.

The Society is fully insured to an unlimited extent against all adverse costs and damages which may be awarded against Members in any action which the Society undertakes on their behalf.

Annual Subscription: £1. Entrance Fee: 10s. Assets exceed £52,000.
No entrance fee to those joining within 12 months of registration.

Application form, and full particulars, from the Secretary, Victory House, Leicester Square, W.C. 2.

Telephone: GERRARD 4314.

OXFORD MEDICAL PUBLICATIONS

A New (Second) Edition of

THE ANATOMY OF THE HUMAN ORBIT

And Accessory Organs of Vision

By **S. ERNEST WHITNALL**, M.A., M.D., B.Ch. (Oxon.), M.R.C.S., L.R.C.P. (Lond.),
Professor of Anatomy, McGill University, Montreal; late University Demonstrator of Human Anatomy, Oxford.

Contents include:—Part One (Osteology), The Bones forming its Orbit, its Relations, and the Accessory Air-Sinuses of the Nose—Part Two (Eyelids), The Eyebrows, Eyelids, Conjunctiva, and Lacrimal Apparatus—Part Three (Contents of the Orbit), The External Configuration of the Globe, Ocular Muscles, Blood-vessels and Nerves—Part Four (Appendix), The Cerebral Connexions of the Nerves—Bibliography—Index.

Pp. 479. 212 Illustrations (16 in Colour). **25s.** net.

THE FUNDUS OF THE HUMAN EYE

An Illustrated Atlas for the Physician.

By **ERNEST CLARKE**, C.V.O., M.D., F.R.C.S.,
Consulting Surgeon to the Central London Ophthalmic Hospital, etc.; Hon. Fellow, Downing College, Cambridge.

The advent of the luminous ophthalmoscope has now brought ophthalmoscopy within the reach of all, and this instrument is becoming as much a part of the physician's equipment as the stethoscope. But although now it is easy to see the fundus of the eye, it is not so easy to interpret what is seen, and the observer wants a small, handy atlas that he can easily consult. It is hoped that this little book will supply this need. Each plate is printed in natural colours on thin card, bound separately on a linen hinge into the cover, thus allowing the book to open flat at any page. Beneath each plate appears a short description of the condition it illustrates. The fundus is enlarged to a uniform diameter of nearly four inches throughout. Only the commonest fundus changes have been illustrated, and the description of the plates has purposely been made as brief as possible

"*So excellent do we consider Mr. Clarke's atlas that we advise all medical men interested in eye work to procure a copy.*"—MEDICAL PRESS.

51 Colour Plates. Size of Atlas 8¾″×5½″. **18s.** net.

A New (Third) Edition of

A TEXT-BOOK OF PSYCHIATRY

For Students and Practitioners.

By **D. K. HENDERSON**, M.D. (Edin.), F.R.F.P.S. (Glas.),
Physician-Superintendent, the Glasgow Royal Mental Hospital; Lecturer in Psychological Medicine, University of Glasgow; Honorary Consulting Physician in Psychiatry, Western Infirmary, Glasgow; Formerly Senior Resident Psychiatrist, the Johns Hopkins Hospital, Baltimore, and Assistant Physician, Psychiatric Institute of the New York State Hospitals;

and **R. D. GILLESPIE**, M.D. (Glas.), M.R.C.P., D.P.M. (Lond.),
Physician for Psychological Medicine, Guy's Hospital, London; Lecturer in Psychological Medicine, Guy's Hospital Medical School; Formerly Assistant Physician, the Cassel Hospital, Penshurst, Kent; Pinsent-Darwin Research Student in Mental Pathology, University of Cambridge; and Assistant Resident Psychiatrist, the Johns Hopkins Hospital, Baltimore.

"*The valuable text book by Drs Henderson and Gillespie is now the fullest and most satisfactory single exposition of Anglo American psychiatry available*"—THE LANCET.

Pp. 607. **18s.** net.

THE COMMONER NERVOUS DISEASES

For Practitioners and Students.

By **FREDERICK J. NATTRASS**, M.D. (Dunelm.), F.R.C.P. (Lond.),
Assistant Physician, Royal Victoria Infirmary, Newcastle-on-Tyne

"*Should prove extremely useful to both classes of readers . . . A model of clearness and orderly thinking . . The author has done his work well, and the production reaches the high standard we always expect from the Oxford Medical Publications.*"—BRITISH MEDICAL JOURNAL.

Pp. 218. 15 Illustrations, 2 Colour Plates. **12s. 6d.** net.

A New (Second) Edition of

POCKET ATLAS OF ANATOMY

By **VICTOR PAUCHET** and **S. DUPRET.**

The many original features of this work can only be appreciated on actual inspection It consists of a series of plates, many of them printed in colour, depicting all regions of the human body, also individual organs, systems, and structures No text is included, except the necessary marginal keys which appear on each plate The old terminology is used throughout, but B N A equivalents are given in brackets An alphabetical list of plates and a full anatomical index is included In this edition, twenty eight new plates have been added, and alterations and corrections made to others where necessary.

"*To refresh the memory in an odd moment one could not wish for a better prompter, and to those for whom the dissecting room is no longer accessible the clarity and superb draughtsmanship of every plate will carry an especial recommendation*"—BROADWAY (Westminster Hospital Journal)

Pp. 390. 345 Plates, 173 in Colour. Size 7¼″×4½″. **12s. 6d.** net.

INJURIES AND SPORT

A General Guide for the Practitioner.

By **C. B. HEALD**, C.B.E., M.A., M.D. (Cantab), M.R.C.P. (Lond.),
Physician-in-Charge of Electrotherapeutic Department, Royal Free Hospital, Physician to the British Red Cross Clinic for Rheumatism; Consulting Physician in Electrotherapy, Royal Air Force.

"*Dr. Heald's book . . . occupies a niche which so far as we know has till now remained unfilled in the medical literature of this sport loving country. As the ground is so fully and carefully covered, it is likely to maintain its unique position for many years to come, and to prove invaluable to all who have to deal with injuries resulting from any kind of sporting activity.*"—BRITISH JOURNAL OF PHYSICAL MEDICINE.

Pp. 567. 380 Illustrations. **25s.** net.

No entrance fee to those joining within 12 months of registration.

Application form, and full particulars, from the Secretary, Victory House, Leicester Square, W.C. 2.
Telephone: GERRARD 4314.

HENRY KIMPTON'S NEW PUBLICATIONS

VOLUME ONE. *JUST READY.*

TEXT-BOOK OF OPHTHALMOLOGY

By W. STEWART DUKE-ELDER, M.A., D.Sc.(St. And.), Ph.D.(Lond.), M.D., Ch.B., F.R.C.S.,

Surgeon, Royal London Ophthalmic (Moorfields) Hospital; Lecturer in Ophthalmology, St. George's Hospital Medical School; Examiner in Ophthalmology, Royal College of Physicians of London and Royal College of Surgeons of England, etc.

Vol. 1.—The Development, Form and Function of the Visual Apparatus.

Crown Quarto. xxix+1,124 pages, with 1,022 Illustrations, including 7 Coloured Plates. Cloth. Price 63/- net.

While English literature possesses several handbooks of Ophthalmology, it can claim no reference text-book which deals with the entire subject comprehensively and at the same time supplies the practitioner, the student, or the research worker with ready access to original sources of information. Indeed, with the exception of the very large German works of encyclopædic nature and composite authorship, the same may be said of any language. It is with the view of rectifying this deficiency that this text-book has been written.

The work is divided into three volumes. The first volume deals with the development, form and function of the visual apparatus; the second will be devoted to the deformities, diseases and injuries of the eyeball; and the third to diseases of the ocular adnexa, refraction and motor anomalies, the ophthalmological aspects of general medicine and diseases of the central nervous system, physical therapy and operative ophthalmic surgery.

NEW (SECOND) EDITION. *JUST READY.*

A DESCRIPTIVE ATLAS OF RADIOGRAPHS

By A. P. BERTWISTLE, M.B., Ch.B., F.R.C.S.

Second Edition. Revised and Enlarged. Crown Quarto. 580 pages, with 767 original Radiographs. Cloth. Price 42/- net (postage 1/-, abroad 1/9).

"A handsome volume."—BRITISH MEDICAL JOURNAL.

A TEXT-BOOK OF EMBRYOLOGY

By M. T. HARMAN, Ph.D.

Small Octavo. 476 pages, with 284 Illustrations. Cloth. Price 18/- net (postage 9d.).

¶ *The illustrations have been selected with great care with a view to helping to create a mental picture of each topic under consideration.* An appendix of laboratory exercises provides the outlines and adds greatly to the value of the book.

A RADIOLOGICAL STUDY OF THE PARA-NASAL SINUSES AND MASTOIDS

By AMÉDÉE GRANGER, K.C.B., K.C.I., M.D., F.A.C.R.

Royal Octavo. 186 pages, with 113 illustrations. Cloth. Price 25/- net (postage 6d.).

CLINICAL ROENTGEN PATHOLOGY OF THORACIC LESIONS

By WILLIAM H. MEYER, M.D.

Royal Octavo. 272 pages, with 183 Illustrations. Cloth. Price 28/- net. (postage 9d.).

ELECTROTHERAPY AND THE ELEMENTS OF LIGHT THERAPY

By RICHARD KOVÁCS, M.D.

HUMORAL AGENTS IN NERVOUS ACTIVITY

With special reference to Chromatophores

By G. H. PARKER

Demy 8vo. With 19 text-figures. 6s. net

Within recent years the phenomena of colour change in various groups of the animal kingdom have led to a revision of our conceptions of the relationship between the effector systems of the body and their corresponding nerves. In the present work the author gives a connected account of modern work and discusses the secretory activity of the nervous system. The book will be of great interest to zoologists, physiologists, and those concerned with the activities of the central nervous system.

Some Recent Issues of especial interest

INDIVIDUALITY OF THE BLOOD

IN BIOLOGY AND IN CLINICAL AND FORENSIC MEDICINE.

By Professor **LEONE LATTES**, Director of the Institute of Forensic Medicine in the University of Modena.

Translated by **L. W. HOWARD BERTIE**, M.A., B.M., B.Ch. (Oxon.).

From the French Edition of 1929, thoroughly revised and brought up to date by the Author.

Contents include :—" Constitution " and " C [illegible] e Constitution of the Blood —Individual Immunity-reactions in Animals [illegible] Iso-agglutination, Blood-groups in Man, &c.)—The Hereditability of [illegible] no-Anthropological Fact—The Individuality of the Blood in its Clinical Applications (Blood-transfusion, Incompatibility, &c.)—The Individuality of the Blood in Forensic Medicine (Affiliation Cases, Individual Diagnosis of Blood-stains, &c.)—Technique of the Individuality Reactions—Bibliography and Index to Authors—Index.

Pp. 427. 71 Illustrations. **30s. net.**

THE USE OF LIPIODOL IN DIAGNOSIS AND TREATMENT

A Clinical and Radiological Survey.

By **J. A. SICARD**, late Professor in the Faculty of Medicine, Paris, and **J. FORESTIER**, of Aix-les-Bains.

Contents include :—Composition and Properties of Lipiodol—Physiology, Absorption, Elimination—General Technique—Radiological Technique—General Indications and Contra-Indications—Lipiododiagnosis—Spinal Subarachnoid Space—Ascending Lipiodol—Epidural Space—Broncho-pulmonary Cavities—Male and Female Generative Systems—Urinary Tract—Blood-vessels—Abscesses and Sinuses—Nasal Sinuses—Lacrymal Ducts—Minor Applications—Estimation of Secretory Activity of Stomach—Lipiodotherapy—Epidural Therapeutic Lipiodol—Various Forms of Algesia—Arthritis—Enuresis—Suppurating Broncho-pulmonary Cavities—Cold Abscesses and Tuberculosis of Serous Membranes—Bibliography—Index.

Pp. 244. 75 Illustrations, including 64 Radiographs. **16s. net.**

A New (Second) Edition of

THE ANATOMY OF THE HUMAN ORBIT

AND ACCESSORY ORGANS OF VISION.

By **S. ERNEST WHITNALL**, M.A., M.D., B.Ch. (Oxon.), M.R.C.S., L.R.C.P. (Lond.),
Professor of Anatomy, McGill University, Montreal; Late University Demonstrator of Human Anatomy, Oxford.

Contents include :—The Bones Forming the Orbit, its Relations, and the Accessory Air-Sinuses of the Nose—The Eyebrows, Eyelids, Conjunctiva, and Lacrymal Apparatus—The Globe (External Configuration), Ocular Muscles, Blood-vessels, and Nerves—The Cerebral Connexions of the Nerves—Bibliography—Index.

Pp. 479. 212 Illustrations (16 in colour). **25s. net.**

DIAGNOSIS IN JOINT DISEASE

A Clinical and Pathological Study of Arthritis.

By **NATHANIEL ALLISON**, M.D., F.A.C.S.,

Professor of Surgery in charge of division of Orthopædic Surgery, University of Chicago; Formerly Professor of Orthopædic Surgery, Harvard Medical School, and Chief of Orthopædic Service, Massachusetts General Hospital; AND

RALPH K. GHORMLEY, M.D.,

Associate in Orthopædic Surgery, Mayo Clinic; Assistant Professor of Orthopædic Surgery, Mayo Foundation, Rochester, Minnesota; Formerly Instructor in Orthopædic Surgery, Harvard Medical School, and Visiting Surgeon, Massachusetts Central Hospital.

Contents include :—Physiology and Chemistry of Joint Structures—Classification of Arthritis—Classification of Joint Diseases—Tuberculosis—Traumatic Arthritis—Arthritis Associated with " Loose-body " Formation—Pyogenic Infection of Joints—Arthritis of Uncertain Origin—Degenerative Arthritis—Case Histories—Bibliography—Index.

Pp. 207. 50 Illustrations, 9 Plates (6 in Colour). **52s. 6d. net.**

DIAGNOSIS OF CONGENITAL DEFECTS OF THE EYE.*

BY IDA MANN, D.SC., M.B. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE ROYAL LONDON OPHTHALMIC HOSPITAL; OPHTHALMIC SURGEON TO THE ROYAL FREE HOSPITAL.

(WITH ILLUSTRATIONS ON SPECIAL PLATE.)

OPHTHALMOLOGISTS have long been noted for the interest, often purely academic, which they take in developmental aberrations, sometimes of the most minute. The original stimulus to the advance of this branch of the specialty came from Germany whence have always emanated the most painstaking studies and collections of such cases. Of recent years interest has been further stimulated by the discoveries of slit-lamp workers, who emphasise the extreme frequency of slight deviations from the normal, and by the more intensive study of embryology, which has allowed of better understanding of their production. Thus emerge the two points of view from which to consider such conditions, the clinical and the embryological, and it is the aim of this lecture to show how the first and practical outlook may be combined with the second, theoretical, to the benefit of both.

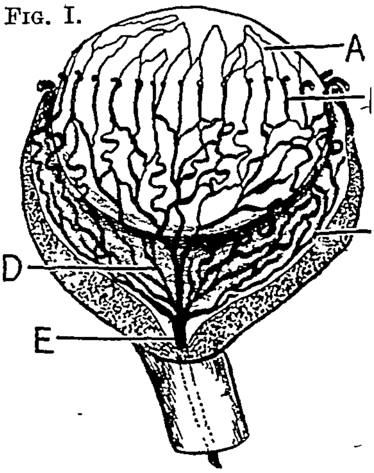
Whoever studies cases of developmental defect of the eye will be struck by the frequency with which they resemble in many ways the results of acquired disease. Conversely many acquired conditions come to reproduce with varying accuracy the possible results of developmental aberrance. The chief interest of the subject lies in the disentangling of the appearances so as to arrive at a knowledge of the past causative agents. In most cases the problem is not an urgent one, since the more dramatic of the acquired diseases usually present no resemblance to congenital defects. Their remote results, however, may come to suggest very strongly certain developmental anomalies. As good an example as any is seen in the fact that pathological pigment on the lens capsule from past inflammatory synechiæ tends after the lapse of years to assume a stellate form indistinguishable in appearance—though often not in position—from the congenital star-shaped pigment cells of minimal persistent pupillary membrane. Thus a past attack of iritis may be misinterpreted and its possible present bearing on the case overlooked. An even more common dilemma—though only likely to puzzle the relatively inexperienced—is that of the diagnosis of medullated retinal nerve-fibres from exudate due to inflammatory or vascular disturbance, especially should they occur in a patient with renal or cardiovascular disease.

In dealing with this question of differential diagnosis it appears advisable to consider the commonest problems in the first place from their anatomical position. On this basis they can be divided into those involving the anterior parts of the eye and therefore visible by focal illumination, and those involving the fundus and only visible ophthalmoscopically. Obviously in some cases both situations present defects, the diagnosis thereby being rendered considerably easier, as when the presence of a doubtful pupillary membrane is made more certain by t presence of a coloboma of the disc in the same eye

Abnormalities Involving the Anterior Part.

It is obvious that the abnormalities involving t cornea, anterior chamber, iris, and lens, cannot dealt with in detail. The most salient only can mentioned here. The majority of congenital a acquired defects in this situation which mig possibly be confused with each other are vascular nature. Such occurrences as visible blood-vessels on the iris, vascular strands, or apparent synechiæ connecting the iris with the lens or cornea, and membranes closing the pupil are all capable of misinterpretation. The first essential in understanding them is a knowledge of the normal arrangement of the fœtal vessels in this region. Fig. I. shows the arrangement of the fœtal intraocul blood-supply at the height of its development. It w be seen that the hyaloid artery entering at the opt disc breaks up into two sets of branches, the va hyaloidea propria, supplying the vitreous, and t network of vessels on the lens, forming its posteri vascular capsule. These latter unite around t equator of the lens and run forwards as the straig parallel vessels of the capsulo-pupillary portion the tunica vasculosa lentis to break up again in two sets of branches, one composed of vessels turni round the margin of the optic cup and draini into choroidal vessels, the other forming loops ov the anterior surface of the lens and constituting t pupillary membrane. The more peripheral loops the pupillary membrane remain as the large supe ficial vessels of the iris stroma, anastomosing at t lesser circle. All the rest of the system disappea

FIG. I.



(A) Pupillary membrane. (B) Capsu pupillary part of vascular capsule. (C, Vasa hyaloidea propria. (E) Hyaloid arte

PERSISTENT PUPILLARY MEMBRANE.

Certain points in connexion with the pupilla membrane should be borne in mind when diagnosi its persistence. In the first place, the vess composing it form a definite radial net connect by an arcade-like arrangement somewhat resembli Gothic arches. They never run either strictly parall or tangential to the pupil margin but always as near radial as possible. The lesser circle of the i represents the arcades back to which the atrop has extended. Any persistence of the membra must therefore show a radial arrangement and attached to the lesser circle.

Secondly, although the vessels are very thin-wall at birth, their coats rapidly thicken and in the pe pheral parts of the membrane which normally persi this thickening is sufficient to hide the colour of t blood stream entirely. Sometimes these vess dilate—in early iritis, sometimes only from irritation due to a corneal foreign body, and sometimes in fair-complexioned people as a permanent condition—but even then the walls can easily be seen as definite white lines on either side of the blood column. In cases of pathological formation of new vessels on the iris, on the other hand, the vessel walls are usually almost invisible.

---

* The Richard Middlemore lecture delivered at the Birmingham and Midland Eye Hospital on Dec. 31st, 1931.

Thirdly, remains of pupillary membrane may appear under a very large variety of forms, ranging from complete persistence of the whole structure to the presence of a single minimal tag attached by one end to some portion of the lesser circle. This latter form is so common (probably over 25 per cent. of all individuals) as to be considered a normal variation. Sometimes the persistent pupillary membrane is pigmented. This is not surprising, for it is morphologically a part of the iris stroma. It should be possible to recognise that this pigmentation is of mesodermal type and is not uveal, but this may be difficult intra vitam. Again the persisting portion of the membrane may be small and adherent to the lens capsule. For this reason the presence of pigmentation in an apparent synechia is no criterion of its inflammatory origin. Its peripheral attachment and general arrangement will prove a much safer guide. (Very occasionally where the whole pupil has at some time been blocked by exudate an inflammatory synechia may be attached to the lesser circle instead of to the pupil margin. This is usually not misleading since it is only found in eyes with gross evidence of disease.)

PATHOLOGICAL CONDITIONS SIMULATING PERSISTENT PUPILLARY MEMBRANE.

It might be thought from the foregoing remarks that given an exact knowledge of the appearance of the fœtal iris, the diagnosis of pathological conditions should be easy. There are, however, in my experience three conditions which may in their final results lead to permanently visible vessels on the iris and so prove misleading. They are, in order of frequency, thrombotic conditions (usually of the vena centralis retinæ and/or one or all of the venæ vorticosæ), past severe iridocyclitis, and trauma in early life.

The *thrombotic* cases are usually immediately diagnosable by their history (sudden onset in middle or later life with immediate impairment of vision and usually rise of tension) but they are interesting on account of the arrangement of the visible vessels. In incomplete cases the vessels visible are merely dilated stroma vessels of the iris. In more severe cases they are actually vessels of new formation, thin-walled, very numerous, and arranged on a plane superficial to the stroma and running often almost at right angles to the stroma vessels and in an entirely haphazard way. Fig. II. (on the Plate) shows them in a typical case. The patient was a man of 54 who had had a thrombosis of the venæ vorticosæ of the right eye eight weeks previously. The tension was raised but there was no pain. It will be seen that the main vessels arise at the periphery in the inferior quadrant and crossing the radial vessels at right angles run a course parallel with the periphery of the iris towards the horizontal meridian, where they break up into a dense plexus of capillaries. In places dilated stroma vessels can be seen running radially and anastomosing with this newly formed plexus. In more severe cases or after a longer time newly formed vessels may leave the iris margin and encroach on the pupil area. They form irregular leashes in most cases and do not resemble normal pupillary membrane vessels nearly as much as do the new vessels in the second (inflammatory) group of cases now to be dealt with.

The *inflammatory* cases are usually due to irido-cyclitis of long standing, often tuberculous. They form a very interesting group, worthy of greater attention from a pathological point of view than it is possible to give them here. For our present purpose their importance lies in the fact that the first apparently new vessels to become visible are merely dilated superficial stroma vessels—i.e., peripheral part of pupillary membrane—while subsequently entirely new vessels bud centrally from these and attempt to reproduce with a varying amount of success the previously atrophied central loops on the pupil area. The similarity of the new membrane—cyclitic membrane closing the pupil and subsequently thinning considerably—to a normal pupillary membrane of the fifth to sixth month of intra-uterine life is often very striking. In some cases even the anastomoses with the capsulo-pupillary vessels curling over the edge of the iris is reproduced. Fig. III. (on Plate) shows such a case. The patient was a man of 48, who had had a severe irido-cyclitis following an injury at the age of 9 (whether perforating or not was not known). There was no clinical evidence of perforation. In this case the new vessels all lie just superficial to the stroma. The loops over the pupil are almost exactly like those of a normal pupillary membrane at six months. A number of large vessels pass behind the iris by curling round between it and the lens as do the palisade vessels of the capsulo-pupillary membrane. The case could, however, be distinguished from a congenital condition even if the history were not known, by at least two criteria. In the first place the pupillary loops do not come off the lesser circle but are directly in continuity with the radial vessels. Secondly the vessels passing backwards round the edge of the iris are much too large relative to the pupillary loops, and they do not anastomose with these as peripherally as they should, or in as regular a manner. If further evidence were needed the thinness of the vessel walls and the absence of pigment must also be taken into account.

The traumatic cases are possibly always associated with a past irido-cyclitis, though this is not always evident, since the need for differential diagnosis in these cases obviously never arises until long after the subsidence of all signs of active inflammation. There is often only a vague history of a blow on the eye in childhood. In one case the patient was a myope and the retina of the affected eye was detached. There is almost always an interval of ten years (in two of my cases over 30 years) between the original injury and the subsequent examination which reveals the condition. In some cases there is no history at all, which in itself leads one to consider the possibility of a congenital origin.

CONGENITAL DEFECTS OF THE LENS.

Congenital defects of the lens are usually self-evident and the well-known appearances of lamellar, suture, and coronary cataract need not detain us. There is, however, one type of lens opacity which can arise either as a developmental defect or as the result of trauma in early life. This is the reduplication cataract or "Kalk." In this type there is an opacity on the lens capsule and a reduplication of this deep to it in the substance of the lens. The two opacities are separated from each other by clear cortex through which often runs a narrow stalk uniting them. For this reason it is also sometimes called a collar-stud opacity. The reason for the appearance is the fact that growth of normal lens cortex has taken place after the injury and has separated the originally injured lens fibres from the scar in the overlying capsule. When the condition is traumatic it can obviously occur at any situation. In congenital cases it is almost always at the equator or at the anterior or posterior pole. In these cases the original adverse influence appears to be pressure—i.e., at the anterior pole pressure against the cornea; at the equator pressure of a capsulo-pupillary vessel; at the posterior pole of an abnormal hyaloid. In making the diagnosis traces of these agents should be sought. In the congenital equatorial Kalks there is in my experience always a coloboma of the iris, which makes the diagnosis simple, unless this be mistaken for the result of an injury also, which is unlikely.

Abnormalities Involving the Posterior Part.

Innumerable descriptions of abnormalities of the posterior part of the eye have been published since the discovery of the ophthalmoscope so that it is unnecessary to go into them in any detail. There are however a few (six) to which attention may be called because both the congenital condition and the acquired, with which it may possibly become confused, are relatively common.

Coloboma of the choroid.—When large in area and found in its typical situation below the disc, will hardly give rise to difficulty in diagnosis, especially as it so often is associated with a coloboma or other abnormality of the iris. The smaller atypically situated colobomata of the choroid are however very likely to be confused with patches of old choroiditis. Indeed, in many cases it is almost impossible to distinguish between them. Nevertheless, there are certain criteria which will assist in deciding whether a lesion is congenital or not—whether it is inflammatory or not is immaterial since many colobomata are possibly due to intra-uterine inflammation. The points to consider are the amount of ectasia, the distribution of the vessels, and the amount of pigmentation. It can in general be said that the earlier in life the process starts the greater the likelihood of ectasia and abnormality of vessels and the less the amount of pigment. Therefore a white ectatic lesion at the macula associated with an abnormal anastomosis between retinal and choroidal vessels in the patch is certainly a macular coloboma. It has arisen in all probability at or before the 100 mm. stage of human development, since this is the stage of appearance of the arteria centralis retinæ. In a case published by Dr. J. A. Ross and myself[1] the time of origin of the patch could be placed with a fair amount of accuracy during the fourth month of intra-uterine life, from a consideration of the concomitant vascular abnormality (destruction of chorio-capillaris and vascularisation of a quadrant of the retina by choroidal vessels). If any remains of the vasa hyaloidea propria are found in connexion with the patch its origin is placed even earlier—i.e., before the normal disappearance of these vessels at the beginning of the third month.

Medullation of the retinal nerve-fibres has already been touched on as being likely to be confused with retinitis. Once the silvery shining striated appearance of the fibres has been recognised there should be no difficulty. The condition is interesting as an example of a developmental anomaly which is not congenital, since it occurs during the first few months of life.

Choroido-vaginal veins.—These are large choroidal veins, resembling venæ vorticosæ, but draining into veins of the sheath of the nerve and visible on the edge of the disc. They appear as flat red streaks and are easily mistaken for hæmorrhages. They are only visible in light coloured myopic fundi, but are possibly much commoner than is thought to be the case.

Persistent hyaloid artery occurs in varying degrees of completeness. It may be mistaken for an inflammatory exudate in Cloquet's canal or for an early retinitis proliferans.

Replacement of the arteria centralis retinæ by cilio-retinal arteries.—In some cases in man and normally in most of the carnivora the retina is supplied by cilio-retinal arteries only. Since these appear suddenly at the edge of the disc, the centre being avascular, the condition may easily be mistaken for a pathological cupping of the disc with extreme kinking of the vessels at the margin.

Pseudo-neuritis is a slightly blurred raised appearance of the disc seen sometimes in healthy hypermetropic eyes. It is probably due to congenital smallness of the foramen scleræ. It may be mistaken for papillœdema unless it is borne in mind that its swelling is barely measurable and that there are never any appearances suggesting hæmorrhage.

There are of course many other conditions which, occurring congenitally, may yet be confused with acquired conditions of greater import. With these I cannot deal here; but in conclusion it may be again pointed out that a knowledge of normal embryology can be possibly of greater assistance in ophthalmological diagnosis than in examining almost any other region or organ.

DIAGNOSIS AND TREATMENT OF PINEAL TUMOURS.

WITH REPORT OF A CASE.

By Wilfred Harris, M.D. Camb., F.R.C.P. Lond.,
PHYSICIAN FOR NERVOUS DISEASES TO ST. MARY'S HOSPITAL AND TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE, LONDON;

AND

Hugh Cairns,* M.B. Adelaide, F.R.C.S. Eng.,
ASSISTANT SURGEON TO THE LONDON HOSPITAL AND TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE, LONDON.

(WITH ILLUSTRATIVE PLATE.)

Tumours of the pineal body are sufficiently rare to remain as pathological curiosities, although records of no less than 113 cases were collected by Haldeman[21] in 1927. It is only within the last 25 years that knowledge of the symptomatology produced by pineal tumours has become sufficiently crystallized to afford reasonable grounds for an accurate diagnosis, since the writings on the subject by Frankl-Hochwart, Hinds Howell, Pellizzi, and more recently by Foerster, Horrax and Bailey, and others. The pineal gland lies immediately above the quadrigeminal plate and the aqueduct of Sylvius, and tumours arising in it may be expected to produce firstly symptoms of obstructive hydrocephalus, from obliteration of the aqueduct by pressure, and later, symptoms of pressure on the superior corpora quadrigemina. Persistent headache, occasional giddiness, and papillœdema are likely to be followed by ptosis, limitation of

* Working under a grant from the Rockefeller Foundation.

upward movement of the eyes, and loss of pupillary reaction to light. Pressure on the inferior corpora quadrigemina may give rise to disorders of hearing, as in our case.

Pineal tumours were formerly thought to be inoperable, but in the last 15 years attempts have been made to remove them by Dandy, Foerster, van Wagenen, and others with increasing success. The methods of exposure of the pineal region have been fairly well worked out, but further surgical experiences are required before the operation may be considered safe and free from the risk of serious disturbance of cerebral function. The vein of Galen is in intimate relation with the tumour, and if it is damaged death is likely to follow. As our case shows, serious consequences may also follow damage to its tributaries.

Report of Case.

The patient, a male aged 20, was first seen on March 16th, 1930, referred by Dr. J. S. Boden on account of headache, double vision, and papillœdema.

HISTORY.

His boyhood had been healthy and the only trouble of possible bearing on his illness was that between the ages of 16 and 19 he had had six attacks of momentary unconsciousness, each of which occurred on rising in the morning and without any warning. For six months before he came under observation he had had occasional giddiness on rising in the mornings, but this did not interfere with his activities in any way. On Feb. 24th, 1930, while out duck-shooting early one morning, he was overcome by severe throbbing pain in the back of the head which lasted for two hours. Thereafter similar attacks occurred each day at 4 A.M. and in one of these he vomited. Early in March, 1930, the headache became particularly violent and began to occur in the middle of the day as well as in the early morning. The pain spread to the right shoulder and there was difficulty in flexing the neck. At this time also he began to see double. He consulted Dr. Boden, who found that he had papillœdema and at once sent him to one of us (W. H.). Throughout his short illness he had heard a noise, like the noise of a sea-shell or a cork rattling on the window pane, whenever he was recumbent. It was heard in the ear that was against the pillow and persisted until he moved his head. On one occasion when the headache was particularly severe he staggered while walking, and at the same time felt as if he had taken too much alcohol. At other times he was quite steady in walking. His mother noticed that he was becoming somewhat hypochondriacal.

He was admitted to the nursing home on March 17th, 1930. The fundi showed bilateral papillœdema (right 5 D., left 4 D.). There was diplopia corresponding to paresis of the left inferior oblique, but no strabismus or nystagmus. There was slight incoördination of the left hand but no weakness. The knee-jerks and plantar reflexes were normal. The diagnoses considered at this time were tumour of the vermis, serous meningitis, and endothelioma of the dura of the posterior fossa.

Lumbar puncture yielded fluid under pressure which contained 30 white cells per c.mm. and a trace of globulin. This suggested the possibility of serous meningitis. At a second lumbar puncture two days later 30 c.cm. of fluid under pressure were withdrawn, but at a third, after another interval of two days, no fluid could be obtained except by aspiration. He remained under observation for six weeks. After the lumbar punctures headaches were less severe and the papillœdema receded about 1 D. Subsequently the papillœdema became worse and surgical intervention was obviously required if vision was to be saved.

EXAMINATION AND DIAGNOSIS.

April 25th, 1930.—The patient was a thin intelligent boy. His head was not enlarged. The occiput was rotated slightly towards the left and the muscles on the left side of the back of the neck were rather prominent. Acute flexion of the neck was painful. There was bilateral papillœdema of 5 diopters with old and recent hæmorrhages, but with each eye he could read Jaeger 1 at ordinary reading distance. The right pupil was slightly larger than the left, and both reacted rather sluggishly to light, but well on convergence. There was a squint and slight weakness of the outward movement of the left eye. Upward movement of the eyes appeared to be slightly defective, but not so much as to be considered significant. There was ptosis of both upper lids which were rather swollen. Whispers were heard at 5 ft. from each ear. His gait was normal, but the limbs were hypotonic, and on the left side slightly ataxic. Apart from some diminution of all the abdominal reflexes, cutaneous and tendon reflexes were normal. No disturbance of sensibility was detected. There was no abnormality of the external genital organs.

Radiography of the skull showed slight increase of convolutional markings and erosion of the dorsum sellæ. The pineal shadow was unusually well seen in view of his age, but it was not enlarged or displaced.

The history and examination indicated a rapid and severe rise of intracranial pressure. Such localising signs as could be detected were considered to indicate a lesion in the cerebellum, but at the same time it was felt that the poor reaction of the pupils to light and the weakness of upward movement of the eyes raised the alternative possibility, of a lesion in the quadrigeminal region. However, after further examination it was considered that these signs were not present in sufficient degree to warrant a diagnosis of quadrigeminal lesion, especially as there was no trace of deafness. After consultation with Dr. Gordon Holmes we decided to explore the cerebellum.

LEGENDS OF ILLUSTRATIONS ON SPECIAL PLATE.

FIG. III.—Lateral view of the skull, showing extensive but localised bony changes in the parietal and occipital regions, with patchy absorption and considerable new bone formation.

FIG. IV.—The left hand, showing osteitis fibrosa of the first, fourth, and fifth metacarpals, and phalanges. All the epiphyses are joined almost five years before the usual time.

FIGS. V. AND VI.—Lateral and antero-posterior views of the thorax, showing osteitis fibrosa and deformity of the spine and ribs. The angulation, causing pressure on the spinal cord, is at the fourth dorsal vertebra.

FIRST OPERATION.

April 26th, 1930. (Intratracheal ether, gas and oxygen anæsthesia.)—During induction of anæsthesia there was considerable increase in the rotation of the occiput to the left. The posterior fossa was exposed by the Cushing cross-bow method. At the outset both lateral ventricles were tapped and from each came a large amount of cerebrospinal fluid under greatly increased pressure, thus confirming the clinical diagnosis of bilateral symmetrical hydrocephalus. On opening the dura the cisterna magna, which was rather large, was found to contain small air bubbles. These could only have come from the lateral ventricles as a result of tapping. This observation thus demonstrated the patency of the aqueduct of Sylvius and fourth ventricle, and was considered at the time, wrongly as it now proves, to exclude a pineal tumour. Both cerebellar tonsils were displaced downwards, the right rather more than the left, but neither of them had actually passed through the foramen magnum. The vermis was incised but no tumour was found in the fourth ventricle. A wide decompression having already been made the incision was closed.

POST-OPERATIVE COURSE.

There was rapid subsidence of the papillœdema and when the patient left the nursing home, 23 days after the operation, the swelling of the discs measured 0·5 to 1 D. Visual acuity was 6/9 in each eye, but he still saw double when looking to the left. Headache disappeared. Certain changes were now evident in the clinical picture. Vomiting which before operation had been remarkably infrequent now occurred each morning. The reaction of the pupils to light became very sluggish, especially on the right side, and convergence and upward conjugate movement of the eyes were now grossly defective. The abdominal reflexes could not be obtained on the left side and the left plantar reflex was occasionally extensor. His walking was not so steady as it had been before operation; he tended to fall to left or right, and he swayed when standing still. There was also slight spasticity of the lower limbs and of the left upper limb, but this disappeared before discharge.

These signs established fairly definitely the diagnosis of tumour in the pineal region. However, during the next five months he gradually improved. Apart from frequent vomiting he was free from discomfort, and by September, 1930, he was walking two miles

and the gas and oxygen withdrawn the patient immediately recovered consciousness. At the same time his pulse-rate became rapid and uncountable and his blood pressure could no longer be registered at the brachial artery. A blood transfusion of 250 c.cm. citrated blood was given, but it is doubtful whether it materially improved the patient's condition for he had not lost much blood during the operation and his colour was good.

PATHOLOGICAL EXAMINATION.

The tumour (S.D. 2468, 1930) was examined by Dr. Dorothy Russell.

Macroscopic.—The tumour (Fig. III.) after fixation consisted of an ovoidal mass, measuring 2·8 × 2·3 × 2·2 cm. Its surface was finely lobulated and appeared to be covered by a thin transparent capsule and a few fine blood-vessels. The cut surface was composed of firm, homogeneous, finely granular yellow tissue which was semi-translucent at the margin and gradually became more opaque towards the centre. In the centre there were several points of calcification and a few minute cysts, up to 0·2 cm. diameter, which contained clear honey-like material. In addition to the main tumour there were numerous fragments, up to 0·8 cm. diameter, which had been collected from the posterior end when an attempt was being made to remove the tumour piecemeal. The total weight of the tumour was 8·75 g.

Microscopic.—Portions of the tissue were fixed in saline formaldehyde, Zenker's fluid, and in formalin-ammonium-bromide. Paraffin sections were stained in hæmatoxylin and eosin, iron hæmatoxylin and van Gieson's mixture, Weigert's fuchselin and neutral red, Mallory's phosphotungstic-acid hæmatoxylin, and Laidlaw's method for reticulum. Frozen sections were stained by Herxheimer's method for fat, Hortega's silver method for pineal parenchyma, and Cajal's gold chloride sublimate method.

The tumour is a non-encapsulated mass composed of a variety of different types of cells. The most abundant type is the so-called "pineal parenchyma" cell (Fig. IVA.), a large cell with finely or coarsely vacuolated, non-fibrillated cytoplasm and a relatively large nucleus containing from two to four conspicuous nucleoli and a close mesh of exceedingly delicate chromatin threads. There are no blepharoplasten. These cells are often seen in mitotic division and occasionally multinucleate giant cells are present. They are aggregated in solid masses of variable size, separated by a connective tissue stroma in which collagen fibres and an abundance of fine reticulum are demonstrable (Fig. VA.). At many points in this stroma are conspicuous focal collections of cells that are indistinguishable from small lymphocytes (Fig. VB.). In some portions of the tumour there are also groups of spindle or irregularly stellate neuroglial cells with a cytoplasm that is more deeply stained and more homogeneous than that of the pineal parenchyma cells (Fig. IVB.). The cytoplasm of these cells contains fibrils but no blepharoplasten. They bear some resemblance to fibrillary astrocytes, but are not impregnated by Cajal's method. Transition between these cells and the pineal parenchyma cells cannot be excluded. Hortega's silver method for pineal parenchyma does not show any cells with characteristic club-shaped processes. In one area near the centre of the tumour is a collection of irregularly shaped deposits of amorphous hæmatoxyphil material, presumably calcium.

This tumour thus clearly belongs to the type described by Bailey and others as pinealoma. Its histological structure bears a remarkable resemblance to that of a common tumour of the testis, variously described under the term alveolar sarcoma, séminome, spheroidal-celled tumour, and so forth. Some years ago one of us (H. C.) brought forward evidence which suggested that the spheroidal-celled tumour of the testis was a tumour of toti-potent cells (THE LANCET, 1926, i., 845). The type cell in this tumour is large, its cytoplasm is vacuolated, and its nucleus, often dropsical, contains one or more conspicuous nucleoli. The cells have a solid acinar arrangement, and the acini are separated by a network of collagen and reticulum around which are collected many small lymphocytes. The appearances, in fact, are practically identical with those of "pinealoma." In our case there were no clinical signs of disorder of the testis and there was no reason to suppose that the pineal tumour was a metastasis. The resemblance between the two types of tumour may be fortuitous, especially as Bailey and Horrax claim to have demonstrated processes on the "pineal parenchyma" cells of some of their tumours. However, we were not able to demonstrate any of the characteristic club-shaped processes in the cells of this tumour, although successful preparations were obtained from a normal gland used as a control. In view, therefore, of its close resemblance to spheroidal-celled tumour of the testis we are not able to exclude the possibility that this pineal tumour is a tumour of toti-potent cells. It may be more than coincidence that both the pineal gland and the testis, organs which are concerned with sexual function and which are known to give rise to teratomas, also give rise to spheroidal-celled tumours that bear a strong resemblance to one another.

POST-OPERATIVE COURSE.

When the patient was put back to bed five hours after the conclusion of the operation his pulse-rate was about 170, rectal temperature 103·8° F. He was conscious and moved all four limbs voluntarily, the right better than the left. Sensation to pin-prick was definitely diminished on the left side. His eyes were deviated to the right and downwards, and he could not move them to the left; this persisted for two days.† Occasional involuntary movements of the right upper and lower limbs occurred during the night.

On the day following operation his temperature fell to 100° and his pulse-rate to 110, but turning him from side to side still affected his general condition adversely. He now developed complete flaccid paralysis of the left upper and lower limbs and slight left lower facial weakness. This persisted for ten days, then he began to move the arm and in a few days the leg. During this stage of hemiplegia he was often drowsy, at times noisy and incontinent, and his temperature showed occasional rises to 102° F. Punctures of the left lateral ventricle and lumbar subarachnoid space were done at frequent intervals. When he could be tested it was found that he had a complete left homonymous hemianopia, a defect of postural sensibility in the left lower and to a less extent in the left upper limb, astereognosis and impairment of tactile localisation of the left hand. The disturbance of sensibility gradually decreased as did the hemiplegia, but the hemianopia remained, and doubtless because of its sudden onset, seriously interfered with his vision although visual acuity was considerably improved.

At the end of the fourth week after operation the drowsiness and incontinence had quite disappeared and his mentality was almost normal though his memory for recent events was still poor. He v[illegible]pital a week later. His headaches, [illegible] had entirely disappeared. The [illegible] was soft and no longer bulging.

After returning home he soon began to walk, and the left hemiplegia gradually disappeared, the last to recover being the left foot and ankle which for some weeks resembled a peroneal palsy. The impairment of postural sensibility persisted. Visual acuity was 6/18 in each eye, but there was complete left homonymous hemianopia, bisecting the macula, and he lost the place when reading. The visual disability was doubtless increased by the fact that there was scarcely any recovery of upward movement of the eyes. The pupils did not react to light and there was no convergence. Lateral conjugate movements were normal and ptosis had to a large extent disappeared. There was great improvement in hearing so that he could now hear whispers 8 ft. from each ear. In view of possible damage to the isthmus of the right limbic lobe from division of the right internal occipital vein it is of interest to record that smell at the right nostril was unimpaired.

During the next nine months he gained in weight and strength and apart from occasional slight giddiness when walking and occasional attacks of headache he remained free from discomfort. However, he was still unsteady in walking and had great difficulty in reading through losing the place, doubtless because of the hemianopia. No further recovery of ocular movements occurred. In June, 1931, nine months after operation, he began to go deaf once more, the cerebellar decompression became tense, and he became extremely unsteady in walking. X ray treatment was given by Dr. M. H. Jupe, but the full dose could not be administered as he would not keep still during treatment. However, he improved considerably until the end of July when he had a fall followed by unconsciousness. He went to the seaside and when seen again in September he was drowsy, apathetic, very deaf, and quite unable to walk. The cerebellar decompression was bulging and tense and he now showed nystagmus to the right. Further intensive X ray treatment was given under Nembutal anæsthesia. After this there was rapid improvement. Hearing became normal at each ear. He was able once more to walk by himself and he became alert and cheerful. The cerebellar decompression receded. When last seen on Dec. 7th, 1931, the improvement was being maintained under X ray treatment.

---

† Temporary deviation of the eyes to the right after removal of the tumour occurred also in Foerster's case.

Comment.

The result of removal of this pineal tumour leaves much to be desired, but the progress of the patient after operation indicates clearly improvements that may be made in the management of future cases. This type of pineal tumour is evidently very susceptible to X ray treatment, and we would doubtless have obtained a better result from operation if we had given X ray treatment persistently both before and after operation as van Wagenen [20] did in his case. Our case shows some of the complications that may arise from this method of approach to the pineal region.

Hitherto very few pineal tumours appear to have been removed. Dandy [4] has removed two, Foerster [7] [8] and van Wagenen [20] have each removed one. Ernest Sachs [18] has also removed a cystic tumour from the pineal region. Cystic tumours of the pineal gland or quadrigeminal region have been evacuated by Pussep [16] and Foerster.[7] In these papers, with the important exceptions of those of Foerster and van Wagenen, no detailed account of the condition of patients that survived the operation is given. It is desirable that stigmata arising from the operation should be reported in order that attempts may be made to avoid them in the future.

Operative Problems.

From a study of the pathological reports of Hinds Howell,[10] Horrax and Bailey,[13] [14] Globus and Silbert,[9] and others, it is clear that in a considerable number of cases attempts to remove pineal tumours would not be likely to succeed. Some of the tumours are vascular and may invade the third or fourth ventricles, either directly or by implantation. Some spread in the subarachnoid space, thus encircling the brain stem, and in one of Globus and Silbert's cases the tumour had a large extension into the right lateral ventricle. In a few cases pineal tumour has been associated with another intracranial tumour, for example, glioma of the optic chiasm (Horrax and Bailey). But there are other pineal tumours which are circumscribed and relatively avascular and which, as Gordon Holmes [11] pointed out in 1910, lie more or less free on the quadrigeminal plate. With modern methods there should be a reasonably good chance of removing these tumours successfully. In other cases a cyst will be found. Probably about one-third of the tumours are of a type that is favourable to operation.

Various methods of surgical approach to the pineal region have been advocated. Krause [15] explored the pineal region along the upper surface of the cerebellum, but was unable to remove the tumour. The method attempted by Brunner ‡ and developed by Dandy [4] and Foerster appears to be superior to the others, and it was the method employed in this case. The posterior half of the right, or in special circumstances the left, hemisphere is exposed. Its venous attachments to the superior longitudinal sinus are divided, and the hemisphere is then retracted outwards so as to expose the splenium of the corpus callosum and the adjacent tentorium. Beneath these lies the tumour. The most difficult part of this operation has been the division of the veins passing into the superior longitudinal sinus without severe bleeding, but the use of endothermy, as advocated by Cushing,[3] renders this step relatively easy. In our case all the veins passing into the superior longitudinal sinus as far forward as the Rolandic fissure were divided, but we subsequently found that it was not necessary to go so far forward. The long axis of a pineal tumour and of the overlying corpus callosum and tentorium is not horizontal, as one is apt to think, but runs usually in an upward and forward direction. The region is best approached not from above, but from above and behind along the most posterior part of the medial surface of the cerebral hemisphere. We believe that the temporary hemiplegia that came on several hours after operation in our case was due to cerebral œdema from division of so many veins, and it would probably have been avoided had we spared the Rolandic vein (vein of Trolard).

Van Wagenen [20] has recently exposed and successfully removed a pineal tumour through the right lateral ventricle. An incision was made through the outer surface of the right cerebral hemisphere and the lateral ventricle was opened at the junction of its occipital and temporal horns. The tumour was then seen as a bulging area covered by the medial wall of the ventricle. This method of exposure would probably not have been effective in our case where the tumour was for the most part lying beneath the tentorium. In van Wagenen's case, as ventriculograms had shown, the tumour projected forwards into the third ventricle. The disturbance of function after operation in his case was the same as in our case—namely, contralateral hemiplegia and sensory loss, and permanent homonymous hemianopia.

Preservation of the vein of Galen is probably essential to life, for on its integrity depends the drainage of blood from the choroid plexuses and from the greater part of both hemispheres, with exception of the cortex. In removing a large pineal tumour Dandy [4] was forced to resect the large and small veins of Galen, and the patient died 48 hours later, though whether as a consequence of this step is not clear. In van Wagenen's case the tumour is figured as lying entirely above the vein of Galen and its tributaries. In Foerster's case the vein of Galen was displaced to the left. Our case in which the tumour lay below the vein of Galen and tela choroidea is probably the more usual type, since this is the normal relationship of the pineal gland and the vein.

A question of considerable importance in the treatment of pineal tumours is raised by the occurrence of left homonymous hemianopia as a result of operation. There was not in our case the slightest abrasion of the visual cortex or of any other part of the inner surface of the hemisphere, which was protected throughout the period of its retraction. The hemianopia was almost certainly due to division of the internal occipital vein, without which the tumour could not have been removed. Most anatomical text-books do not mention this vein, though it is figured by Charpy [2] in a diagram which we have modified to show the relationship of the vein to the pineal tumour in our case (Fig. II.). The internal occipital vein in our case appearing as a congeries of vessels covered by thickened arachnoid, has a short course from the internal surface of the hemisphere near the anterior end of the calcarine fissure to the vein of Galen, and in our case was lying above the tumour and preventing its exposure from above. We were fortunate enough to interest Prof. G. Elliot Smith in our suspicions as to the production of hemianopia by division of this vein and he and Dr. Una Fielding found by injection experiments that it drains the greater part of the area striata. In its course towards the vein of Galen it comes in close relationship with the under surface of the splenium and the tip of the pineal body. Save in the most anteriorly placed pineal tumours the problem of avoiding injury to this vein with resulting contralateral hemianopia is likely to be one of great difficulty.

---

‡ Brunner's case is described by Rorschach.[17]

Diagnostic Problems.

It is not necessary here to recapitulate the signs of pineal tumour which are admirably described by Hinds Howell[10] and more recently by Foerster.[7] Our case shows that deafness resulting when the posterior quadrigeminal bodies are compressed by the tumour is not necessarily bilateral, as Horrax[12] suggested. Perhaps it would be more correct to say that the disturbance of hearing in the two cases may be so unequal that one ear may hear almost normally while the other is almost completely deaf. Sexual precocity occurs with some pineal tumours, particularly with *pineal teratomas in boys, and this has been described* by, Frankl-Hochwart,[10] Horrax and Bailey,[14] and others.

In an advanced case the clinical picture of a pineal tumour is fairly easy to recognise, but by that time the patient is usually almost or quite blind. The early cases are difficult to diagnose because at a time when papillœdema and other signs of hydrocephalus are already intense the only localising signs to be observed are slight ptosis and slight sluggishness of the pupillary reactions to light. The difficulty is increased by the fact that such partial ocular palsies are not always due to a lesion in the pineal region. In a case recently under the care of one of us these signs, together with impairment of upward movement of the eyes and signs of raised intracranial pressure, suggested strongly a pineal tumour, but operation disclosed an angeioma of the right lateral lobe of the cerebellum. Pineal and cerebellar tumours may simulate one another closely.

Dandy[5] claims that ptosis is the first sign and that "when ptosis is bilateral and without further involvement of the other muscular functions of the oculomotor nerves, the findings are practically pathognomonic of a tumour pressing down from the region of the corpora quadrigemina or pineal body." He also claims that localisation of pineal tumours is now relatively simple by ventriculography. This is evidently a promising field, but diagnosis by this means is scarcely as simple as Dandy's somewhat categorical statements suggest. The interpretation of ventriculograms of the third ventricle requires great experience, and even then may be difficult. Furthermore, it is unlikely, as Dandy affirms, that pineal tumours will always produce a filling defect of the third ventricle, for some of them grow backwards beneath the tentorium rather than forwards into the third ventricle. It may still be impossible after ventriculography to say whether the tumour is in the pineal region or is in the cerebellum. When we consider also that the use of air for localisation of tumours that produce intense hydrocephalus is not without its dangers and should be followed promptly by operation, it is doubtful whether ventriculography will really solve the problem of diagnosis in every case.

In a few cases pineal tumour has been associated with severe thirst, polyuria, obesity, and signs of pressure on the optic chiasm, thus simulating a tumour in the hypophyseal region. But the majority of cases simulate a cerebellar tumour and the main diagnostic problem in most cases will be whether to do a preliminary cerebellar exploration and to explore the pineal region later if no lesion of the posterior fossa is found, or whether to explore the pineal region at once. In our case, it will be recalled, considerable symptomatic improvement followed cerebellar decompression, and at the same time papillœdema subsided. When symptoms of hydrocephalus recurred and vision began to fail the signs of pressure on the quadrigeminal bodies were definite, and it was possible to localise the tumour accurately and to plan with deliberation an operation for its removal. Furthermore, we formed the impression that the cerebellar decompression acted as a valuable safety-valve during the stormy days that followed removal of the tumour.

It might be thought, therefore, that the right course to pursue in every case in which the diagnosis was not absolutely certain on clinical grounds would be to do a cerebellar exploration decompression and then to wait for some definite clinical signs before making a direct attack upon the tumour. In this connexion, however, it is important to note that four of Cushing's *cases, reported by Horrax and Bailey,*[13] [14] *died* at varying periods up to nine days after cerebellar decompression. The differences in effect of cerebellar decompression in pineal tumours are probably to be explained in part at least by the differences in size and in position of individual tumours in relation to the various parts of the mid-brain. After cerebellar decompression the tumour will tend to be displaced backwards. In tumours that have already expanded backwards beneath the tentorium this may relieve the pressure on the aqueduct of Sylvius and on adjacent structures. When the tumour has grown forwards into the third ventricle the effect of cerebellar decompression may be to produce increased pressure of the tumour against the aqueduct and quadrigeminal plate. Such shifting of the tumour will surely produce changes in the clinical picture and early exploration of the pineal region after a negative cerebellar exploration might still save the patient. The advantages that may come from careful neurological examination of patients with intracranial tumours after negative intracranial explorations have been pointed out in a previous paper (Cairns[1]). In the case now reported the localising signs of pineal tumour appeared almost immediately after cerebellar decompression.

Our conclusion is that diagnosis of pineal tumours and decisions as to the surgical procedure to be adopted in individual cases are still far from easy. In cases that are still doubtful after clinical examinations, or in early cases still doubtful after clinical examination and ventriculography, probably the best surgical procedure is a wide osteoplastic exposure of the cerebellum and posterior portions of the cerebral hemispheres. This can be effected by the type of operation that de Martel[6] uses for exploring the cerebellum, but the incision should extend further up towards the vertex. In this operation if no lesion is found in the posterior fossa it is possible to open the dura over the exposed right occipital lobe and thus to deal radically with any lesion of the pineal region.

Summary.

A youth, aged 20, with a history of four petit mal fits in four years complained of occasional giddiness on rising in the mornings and five months later began to have violent occipital headache. Papillœdema developed rapidly, and localising signs which were inconspicuous suggested a lesion of the posterior fossa or of the pineal gland. Cerebellar decompression was done seven months after the onset of symptoms without any tumour being found. There was rapid subsidence of papillœdema with preservation of good vision, but signs of disturbance of the superior corpora quadrigemina at once began to appear. He remained well for five months but then had another attack of hydrocephalus and signs of pressure on the inferior corpora quadrigemina. At operation an apparently circumscribed pineal tumour was removed, but only after division of the right internal occipital vein near its point of entry into the vein of Galen. After operation there was on the left side hemiplegia and sensory loss which gradually recovered, and left homonymous hemianopia which remained complete. There was relief from headache and from deafness, but great unsteadiness in walking and disturbance of vision, although visual acuity was only moderately impaired. Nine months after the tumour had been removed signs of recurrence became manifest. Under X ray treatment there was rapid improvement which was being maintained when the patient was last seen 13 months after the second operation, that is, two years and seven months after the onset of symptoms. Some problems of diagnosis and treatment of pineal tumours are discussed.

We desire to acknowledge and thank Dr. Dorothy S. Russell for the histological work in this case, and Prof. G. Elliot Smith and Dr. Una Fielding for their valuable help in the anatomical problems raised by this case. The expenses of publication were defrayed by the Charles Bingham Bolton Fund for neurology.

RED CROSS BLOOD TRANSFUSION SERVICE.—The Duke of York, as chairman of the council of the British Red Cross Society, on Dec. 16th presented honorary life membership certificates and badges to Mr. and Mrs. P. L. Oliver in recognition of their work in organising and supervising the Red Cross Blood Transfusion Service. Sir Arthur Stanley recalled that the service began in 1921 as a result of a request for a blood donor received by the Camberwell division of the society, of which Mr. Oliver was then hon. secretary. Mr. Oliver formed a circle of Red Cross members to try to meet the demand, and in 1924 this had increased so much that he had to appeal for outside volunteers. The London Blood Transfusion Service was then formed, with Mr. Oliver as hon. secretary, and since then the service had steadily grown, having now more than 1300 donors on its books. So far, 1980 donors had been supplied during 1931. Mr. Oliver's office, said Sir Arthur, was open night and day, and his telephone has only once been left unattended—during a change of administration in 1926—in the 11 years the service had been in existence.

EARLY DIAGNOSIS OF WHOOPING-COUGH BY THE COUGH-DROPLET METHOD.

WITH A NOTE ON VACCINES AND THEIR USE.

BY A. D. GARDNER, M.D. OXF., F.R.C.S. ENG.,
AND
P. H. LESLIE, M.A.

(From the School of Pathology, the University, Oxford.)

WHOOPING-COUGH is often regarded as an unimportant disease, and few seem to realise that, as a killer of children, it is at least equal to measles, or to diphtheria and scarlet fever put together. In the Registrar-General's Statistical Review we find that the average annual death-rates per 1,000,000 persons living under the age of 15 during the period 1920 to 1929 were: for whooping-cough, 456; for measles, 440; for diphtheria, 322; and for scarlet fever, 79.

Science has hitherto given the physician little help in his management of the disease; the diagnosis usually has to be made by the mother or nurse, and treatment is merely palliative. The aid of bacteriology in diagnosis is rarely called upon, because neither the medical profession as a whole nor laymen, such as heads of schools, with children in their care, know what valuable advances in our knowledge of this subject have been made in recent years.

Now we, like most bacteriologists, were aware that a bacteriological diagnostic method had been successfully practised in Denmark for some years, and early in 1929 we decided to put it to a thorough test with the aim of assisting its introduction into this country. Soon after we had begun our work, a paper on the subject was published by Sugare and McLeod (1929), which partly covers the same ground. We shall refer to this again later.

The Causative Agent.—There is no longer any room for doubt that the bacillus of Bordet and Gengou (1907), or, in modern terminology, *Hæmophilus pertussis*, is the true and sole cause of whooping-cough. In the catarrhal bronchial exudate of persons who sooner or later develop typical symptoms it is invariably present; in catarrhal states unconnected with whooping-cough, never. We believe that these statements are not too strong, although the proportion of cases in which it is practicable to demonstrate the bacterium must always fall short of 100 per cent., and in spite of the fact that it has been found in the throats of two children not evidently suffering from whooping-cough (Fränkel, 1908). The blood-serum of whooping-cough patients constantly contains substances which fix complement specifically with suspensions of *H. pertussis*. In other infections the reaction is negative.

These proofs of its causative rôle have been completed by the transmission of the disease to monkeys with pure cultures of the micro-organism (Fränkel, 1908; Inaba, 1912; Sauer and Hambrecht, 1929). Mallory and Horner (1912) showed that in dead human subjects the bacterium grows on the ciliated epithelium of the trachea and bronchi, and Sauer and Hambrecht (1929) have given a clear demonstration of the resulting endobronchial and peribronchial lesions. *H. pertussis* may be recovered, sometimes in pure culture, from broncho-pneumonic patches in the lungs.

Bacteriological Diagnosis.

Previous Work.—The pioneer researches of the Danes, based upon the discovery of *H. pertussis* by

Bordet and Gengou in 1906, are well summarised by Madsen (1924), and will be mentioned again. In America Lawson and Muller (1927) and Sauer and Hambrecht (1930) have made good use of the diagnostic method, which has also proved very serviceable in France in the hands of Debré, Marie, and Pretet (1929).

When we began our work there was, so far as we know, no British publication on the subject, but shortly afterwards, as we have already mentioned, a paper was published by Sugare and Macleod (1929) who, in spite of using the sputum-plating method, which had been discarded as unsatisfactory by the Danes, isolated the bacterium in all of their five cases in the catarrhal stage. Their paper incidentally contains valuable confirmatory evidence of the invariable absence of *H. pertussis* in catarrhal conditions other than whooping-cough.

The Culture Medium.—We have used the Danish modification of the original Bordet-Gengou medium, altered in a few respects. It is made as follows:—

Potatoes are cleaned and cut into thin slices: 1 kg. of the slices with 2 litres of distilled water and 80 c.cm. of glycerin are boiled until the potatoes are soft. The water lost in the boiling is made up and the whole filtered through linen. The juice is then adjusted to pH 7·0. One part of the neutralised juice and three parts of 0·6 per cent. NaCl are mixed and distributed in flasks, 200 c.cm. in each; 4 per cent. agar is added, and the flasks are left in the cold store overnight. The medium is then autoclaved and to every 200 c.cm. are added 4·5 c.cm. of a sterile N/2 solution of lactic acid (3·72 c.cm. of ac. lact. of sp. gr., 1·21 to 100 c.cm. aq. dest.). When the flasks have been cooled to 45°–50° C., 100 c.cm. of fresh defibrinated horse's blood is added to each. The medium is then mixed well and poured into Petri dishes. It will keep good for a fortnight in the cold store.

COUGH-DROPLET METHOD.

As soon as the earliest suspicion of whooping-cough arises, the doctor obtains from the laboratory two or three Petri dishes of the special culture-medium, and instructs the parent or nurse to carry out the following directions, which are sent out with the culture-medium.

> "When a *natural attack* of coughing starts, remove the glass lid of one of the dishes and, holding the dish about six inches away, allow the patient to cough for about 10–15 seconds on to the surface of the red jelly. No sputum (phlegm) must be coughed on to the surface, otherwise the plate will be spoilt. The *invisible* cough droplets are quite sufficient. Replace the lid at once. Do the same with each of the dishes provided. If the patient has no long attacks, but only a short, sharp cough occasionally, use each dish three or four times. Artificial coughs, done on purpose, are useless. Keep the dishes in a cool, dark place when not in use, and return them as soon as possible to the laboratory."

If necessary, the dishes may be sent out and returned by post. In Denmark it has been found necessary to use metal (aluminium) dishes to avoid breakage. We have found glass ones of about 2¼ in. diameter satisfactory for local use. After the speediest possible return to the laboratory, the dishes are incubated at 37° for about 72 hours, being examined each day to see that the sowing has been satisfactorily done. Any spreading colonies that may spoil the result are cut out of the medium. In about 48 hours *H. pertussis* begins to appear in the form of minute glistening colonies, but 72 hours (occasionally even four days) are required before they can be recognised with any certainty. A watchmaker's lens, which can be held in the eye, is an important aid, and we have found oblique illumination with a dark-shaded lamp preferable to daylight. The fully developed colony is about 0·5 mm. across and has a characteristic sheen, like a tiny pearl or a droplet of mercury. Zones of whitening or of clearing round the colonies, such as are sometimes described, are in our experience inconstant when the growth is young, though ageing growth always whitens the medium at a certain stage. A platinum needle easily enters the colony and picks up part of its moist substance.

IDENTIFICATION OF ORGANISM.

The typical appearance of the colonies nearly always differentiates them from those of any other organism; but sometimes, owing to the dryness of the medium or to delayed development, the colonies appear dry, whitish, and wrinkled, and considerable doubt may arise as to their identity. As a routine, therefore, when films are made from any suspicious colony, a subculture is made on fresh Bordet medium. In the case of *H. pertussis* the mass-growth is dry, roughish, and circumscribed, resembling a streak of aluminium paint. Films are stained by Gram's method, with diluted carbol-fuchsin as counterstain. *H. pertussis* appears as a small ovoid Gram-negative rod or cocco-bacillus, frequently paired, like a tiny pneumococcus. The common allegation of "bipolar staining" seems to be based on a misinterpretation of these paired forms, and it should be omitted from future descriptions of the organism. *H. influenzæ* may be distinguished from *H. pertussis* by the fact that the colonies of the former organism appear after 24 hours' incubation. They are flat and transparent, and slide over the surface of the medium when touched with a platinum needle. Subcultured on Bordet's medium they give rise to a moist, transparent, and spreading growth.

Agglutination.—Although the combination of colony appearance and cell form makes the identification of *H. pertussis* certain enough for practical purposes, we have verified all our identifications with the agglutination test.

Agglutination Test.—From the primary streak of a colony subcultures are made by smearing the growth all over the surface of one or more large dishes of Bordet's medium. After 48 hours at 37° C., the growth is scraped off and emulsified in saline solution containing 0·2 per cent. of formalin, by rubbing up in an agate mortar. After dilution to a suitable density (equal to a suspension of some 600 million per c.cm. of *Bact. typhosum*), the suspension is tested by Dreyer's method with a specific agglutinating serum, in dilutions ranging from 1 in 50 to 1 in 500 or more.

Agglutinating Serum.—Having discovered at the outset that freshly isolated cultures entirely failed to react with serums made from old stock cultures of *H. pertussis* from the National Collection of Type Cultures, we were compelled to investigate the serological structure and variability of the microbe, with results which have been published elsewhere (Leslie and Gardner, 1931).

Briefly, we found that freshly isolated cultures are all serologically alike, and we called their characteristic antigen Phase I. A distinct antigen, Phase II., occasionally replaces No. I. in the early stages of laboratory life. These two phases are toxic to animals, and represent the smooth state of the microbe. Cultures grown and stored on Bordet's medium may preserve their original antigenic constitution for months, but directly they become accustomed to grow on heated blood, egg, or meat-infusion media, the antigen of Phase I. (or II.) disappears, and an entirely different one (III.) takes its place. In old stocks a further change to Phase IV., with a final antigenic alteration, often occurs. These last two phases are non-toxic to guinea-pigs, and represent the rough state. The fundamental features of this change were described long ago by Bordet and his collaborators, but it is only in the light of recently-acquired knowledge of bacterial variation that we have begun to understand it.

To prepare a Phase I. serum, a primary subculture on Bordet's medium from a colony on the original cough plate is made into a suspension for inoculation into a rabbit. Although the resulting serum will partially agglutinate Phase III. in addition to Phase I., this is no disadvantage in routine work. To make a mono-specific Phase I. serum, the heterologous agglutinins must be removed by absorption.

Such serums are quite specific and do not react with *H. influenzæ* or *B. bronchisepticus*. Those made with the final rough Phase IV., however, agglutinate the latter organism to a considerable titre.

Cultural Methods.—On first isolation the organism will not grow on Fildes's medium, whereby it is easily distinguished from *H. influenzæ*. It will usually grow well in serum-broth from the outset. Serum-agar at first supports it but poorly, and when luxuriant growth is established on this medium the antigenic change to Phase III. usually accompanies it. The same is true, it seems, of "chocolate-agar" and other heated blood-media, though we have used these very little.

Cultivation on egg-medium is at first impossible, but the organism can be accustomed to it by repeated heavy transplantations, and always changes from Phase I. to Phase III. in the process. Growth on agar seems to be an exclusive function of the "rough" Phases III. and IV. In broth, two of our Phase IV. cultures grew in extraordinarily long, tangled, unbranched filaments, forming a tenacious adherent mass at the bottom of the tube, and looking microscopically like an unbranched mycelium.

The only way to handle *H. pertussis* satisfactorily for immunological purposes is to keep it growing on Bordet's medium.

Results with Cough-droplet Method.

We have had no local epidemic during the last two years, which accounts for the smallness of our figures, but since these tally so completely with the Danish and American statistics, we have not felt it necessary to collect more ample data.

Tests totalling 107 were done on 82 individuals suspected of whooping-cough. The subsequent clinical course of 30 of these cases was such as to remove the suspicion; and all of our 38 tests on these cases agreed with the negative clinical diagnosis.

Analysing the cases which we accept as whooping-cough on clinical or bacteriological grounds: 12 tests were done in the first week of the illness (catarrhal stage) before the development of any whoop, and of these 9 were positive and 3 negative. One of the latter was technically unsatisfactory. Of 25 tests done in the second week—i.e., about the time when the cough is becoming characteristically spasmodic—15 were positive. Amongst the 10 negatives there was a large proportion (7) of technically unsatisfactory tests. In the third week we had 8 positive and 5 negative results (2 of the latter unsatisfactory). In the fourth week we had 3 negatives and 1 positive; in each of the fifth and sixth weeks, 2 negatives. The remaining 11 negative tests must be excluded from calculation, because the nature of the illness remained clinically uncertain to the end.

If we now take the case as the unit, irrespective of whether it was tested one or more times, we get the following percentage figures, which are shown in conjunction with those of other workers. (See Table.)

It is impossible to be exact in such statistics. The stage of the disease is often very difficult to determine. We are also well aware that it is statistically absurd to state our small series of cases in percentages; yet we have thought it justifiable to do so, in order to demonstrate at a glance the agreement of our results with those of the Danes and Americans. The fact that we have failed to isolate any *H. pertussis* after the fourth week, whereas the Danes still secured a fair percentage of successes, means very little, since we only examined a very few patients in that stage. Sauer and Hambrecht agree with us in that they failed to isolate the organism in all their 40 cases in the phase of decline. The Danish method, it seems, is to use three Petri dishes of medium for each test. We sent out two, and sometimes only one of these was used. Whenever possible, however, we repeated the test if the first result was negative, and if whooping-cough was still suspected.

Successful Isolations of H. pertussis in Cases Proving Clinically or Bacteriologically to be Whooping-cough.

Stage of illness.	A. D. G. and P. H. L. (47 cases).	Danish. (Madsen, 1924.) (914 cases.)	American. (Sauer and Hambrecht, 1930.) (200 cases.)
	per cent.		
1st week . . (Catarrhal phase)	75	75	98 (catarrhal phase).
2nd week . . (Spasmodic phase)	67	57	—
3rd week . .	75	61	65 (spasmodic phase).
4th week . .	25	45	—
5th week . .	0	40	0 (phase of decline).
6th and later .		9	—

We have accepted a definite clinical diagnosis, made either before or after the bacteriological test, as sufficient proof of the identity of the illness. In five cases, however, the manifestations, though sufficient to arouse suspicion, were so atypical that clinical diagnosis was impossible. There is no doubt that these persons would have been passed by their doctors as uninfected and uninfectious had they not been bacteriologically tested. In two other cases the microbe was isolated before the development of characteristic symptoms, when the doctor was still in doubt.

The bacteriological method is therefore not only able to accelerate a diagnosis obtainable eventually by clinical methods, but also to supply one where clinical methods fail.

Determination of Infectivity.—After the sixth week from the onset the production of *H. pertussis* has practically always ceased. But if the cough, particularly of the spasmodic type, persists, the doctor may be hard put to it to advise on the duration of isolation and to decide such questions as whether the child may now go back to school. In cases such as these we recommend three tests on successive days, or two if it is certain that the illness has lasted longer than six weeks. If all the tests prove negative, the child may be considered harmless. We have carried out several examinations of this kind, to the satisfaction of doctors, parents, and school authorities.

Carriers.—There is no doubt that whooping-cough occasionally takes a mild and chronic form which would never be suspected but for some special circumstance. We isolated the microbe from an adult with no disturbance of health beyond a slightly spasmodic cough, who was living in an infected household. In Denmark the headmaster of a school was discovered to have been the cause of a succession of outbreaks

Bordet and Gengou in 1906, are well summarised by Madsen (1924), and will be mentioned again. In America Lawson and Muller (1927) and Sauer and Hambrecht (1930) have made good use of the diagnostic method, which has also proved very serviceable in France in the hands of Debré, Marie, and Pretet (1929).

When we began our work there was, so far as we know, no British publication on the subject, but shortly afterwards, as we have already mentioned, a paper was published by Sugare and Macleod (1929) who, in spite of using the sputum-plating method, which had been discarded as unsatisfactory by the Danes, isolated the bacterium in all of their five cases in the catarrhal stage. Their paper incidentally contains valuable confirmatory evidence of the invariable absence of *H. pertussis* in catarrhal conditions other than whooping-cough.

The Culture Medium.—We have used the Danish modification of the original Bordet-Gengou medium, altered in a few respects. It is made as follows:—

Potatoes are cleaned and cut into thin slices: 1 kg. of the slices with 2 litres of distilled water and 80 c.cm. of glycerin are boiled until the potatoes are soft. The water lost in the boiling is made up and the whole filtered through linen. The juice is then adjusted to pH 7·0. One part of the neutralised juice and three parts of 0·6 per cent. NaCl are mixed and distributed in flasks, 200 c.cm. in each; 4 per cent. agar is added, and the flasks are left in the cold store overnight. The medium is then autoclaved and to every 200 c.cm. are added 4·5 c.cm. of a sterile N/2 solution of lactic acid (3·72 c.cm. of ac. lact. of sp. gr., 1·21 to 100 c.cm. aq. dest.). When the flasks have been cooled to 45°–50° C., 100 c.cm. of fresh defibrinated horse's blood is added to each. The medium is then mixed well and poured into Petri dishes. It will keep good for a fortnight in the cold store.

COUGH-DROPLET METHOD.

As soon as the earliest suspicion of whooping-cough arises, the doctor obtains from the laboratory two or three Petri dishes of the special culture-medium, and instructs the parent or nurse to carry out the following directions, which are sent out with the culture-medium.

"When a *natural attack* of coughing starts, remove the glass lid of one of the dishes and, holding the dish about six inches away, allow the patient to cough for about 10–15 seconds on to the surface of the red jelly. No sputum (phlegm) must be coughed on to the surface, otherwise the plate will be spoilt. The *invisible* cough droplets are quite sufficient. Replace the lid at once. Do the same with each of the dishes provided. If the patient has no long attacks, but only a short, sharp cough occasionally, use each dish three or four times. Artificial coughs, done on purpose, are useless. Keep the dishes in a cool, dark place when not in use, and return them as soon as possible to the laboratory."

If necessary, the dishes may be sent out and returned by post. In Denmark it has been found necessary to use metal (aluminium) dishes to avoid breakage. We have found glass ones of about 2½ in. diameter satisfactory for local use. After the speediest possible return to the laboratory, the dishes are incubated at 37° for about 72 hours, being examined each day to see that the sowing has been satisfactorily done. Any spreading colonies that may spoil the result are cut out of the medium. In about 48 hours *H. pertussis* begins to appear in the form of minute glistening colonies, but 72 hours (occasionally even four days) are required before they can be recognised with any certainty. A watchmaker's lens, which can be held in the eye, is an important aid, and we have found oblique illumination with a dark-shaded lamp preferable to daylight. The fully developed colony is about 0·5 mm. across and has a characteristic sheen, like a tiny pearl or a droplet of mercury. Zones of whitening or of clearing round the colonies, such as are sometimes described, are in our experience inconstant when the growth is young, though ageing growth always whitens the medium at a certain stage. A platinum needle easily enters the colony and picks up part of its moist substance.

IDENTIFICATION OF ORGANISM.

The typical appearance of the colonies nearly always differentiates them from those of any other organism; but sometimes, owing to the dryness of the medium or to delayed development, the colonies appear dry, whitish, and wrinkled, and considerable doubt may arise as to their identity. As a routine, therefore, when films are made from any suspicious colony, a subculture is made on fresh Bordet medium. In the case of *H. pertussis* the mass-growth is dry, roughish, and circumscribed, resembling a streak of aluminium paint. Films are stained by Gram's method, with diluted carbol-fuchsin as counterstain. *H. pertussis* appears as a small ovoid Gram-negative rod or cocco-bacillus, frequently paired, like a tiny pneumococcus. The common allegation of "bipolar staining" seems to be based on a misinterpretation of these paired forms, and it should be omitted from future descriptions of the organism. *H. influenzæ* may be distinguished from *H. pertussis* by the fact that the colonies of the former organism appear after 24 hours' incubation. They are flat and transparent, and slide over the surface of the medium when touched with a platinum needle. Subcultured on Bordet's medium they give rise to a moist, transparent, and spreading growth.

Agglutination.—Although the combination of colony appearance and cell form makes the identification of *H. pertussis* certain enough for practical purposes, we have verified all our identifications with the agglutination test.

Agglutination Test.—From the primary streak of a colony subcultures are made by smearing the growth all over the surface of one or more large dishes of Bordet's medium. After 48 hours at 37° C., the growth is scraped off and emulsified in saline solution containing 0·2 per cent. of formalin, by rubbing up in an agate mortar. After dilution to a suitable density (equal to a suspension of some 600 million per c.cm. of *Bact. typhosum*), the suspension is tested by Dreyer's method with a specific agglutinating serum, in dilutions ranging from 1 in 50 to 1 in 500 or more.

Agglutinating Serum.—Having discovered at the outset that freshly isolated cultures entirely failed to react with serums made from old stock cultures of *H. pertussis* from the National Collection of Type Cultures, we were compelled to investigate the serological structure and variability of the microbe, with results which have been published elsewhere (Leslie and Gardner, 1931).

Briefly, we found that freshly isolated cultures are all serologically alike, and we called their characteristic antigen Phase I. A distinct antigen, Phase II., occasionally replaces No. I. in the early stages of laboratory life. These two phases are toxic to animals, and represent the smooth state of the microbe. Cultures grown and stored on Bordet's medium may preserve their original antigenic constitution for months, but directly they become accustomed to grow on heated blood, egg, or meat-infusion media, the antigen of Phase I. (or II.) disappears, and an entirely different one (III.) takes its place. In old stocks a further change to Phase IV., with a final antigenic alteration, often occurs. These last two phases are non-toxic to guinea-pigs, and represent the rough state. The fundamental features of this change were described long ago by Bordet and his collaborators, but it is only in the light of recently acquired knowledge of bacterial variation that we have begun to understand it.

To prepare a Phase I. serum, a primary subculture on Bordet's medium from a colony on the original cough plate is made into a suspension for inoculation into a rabbit. Although the resulting serum will partially agglutinate Phase III. in addition to Phase I., this is no disadvantage in routine work. To make a mono-specific Phase I. serum, the heterologous agglutinins must be removed by absorption.

Such serums are quite specific and do not react with *H. influenzæ* or *B. bronchisepticus*. Those made with the final rough Phase IV., however, agglutinate the latter organism to a considerable titre.

Cultural Methods.—On first isolation the organism will not grow on Fildes's medium, whereby it is easily distinguished from *H. influenzæ*. It will usually grow well in serum-broth from the outset. Serum-agar at first supports it but poorly, and when luxuriant growth is established on this medium the antigenic change to Phase III. usually accompanies it. The same is true, it seems, of "chocolate-agar" and other heated blood-media, though we have used these very little.

Cultivation on egg-medium is at first impossible, but the organism can be accustomed to it by repeated heavy transplantations, and always changes from Phase I. to Phase III. in the process. Growth on agar seems to be an exclusive function of the "rough" Phases III. and IV. In broth, two of our Phase IV. cultures grew in extraordinarily long, tangled, unbranched filaments, forming a tenacious adherent mass at the bottom of the tube, and looking microscopically like an unbranched mycelium.

The only way to handle *H. pertussis* satisfactorily for immunological purposes is to keep it growing on Bordet's medium.

Results with Cough-droplet Method.

We have had no local epidemic during the last two years, which accounts for the smallness of our figures, but since these tally so completely with the Danish and American statistics, we have not felt it necessary to collect more ample data.

Tests totalling 107 were done on 82 individuals suspected of whooping-cough. The subsequent clinical course of 30 of these cases was such as to remove the suspicion; and all of our 38 tests on these cases agreed with the negative clinical diagnosis.

Analysing the cases which we accept as whooping-cough on clinical or bacteriological grounds: 12 tests were done in the first week of the illness (catarrhal stage) before the development of any whoop, and of these 9 were positive and 3 negative. One of the latter was technically unsatisfactory. Of 25 tests done in the second week—i.e., about the time when the cough is becoming characteristically spasmodic—15 were positive. Amongst the 10 negatives there was a large proportion (7) of technically unsatisfactory tests. In the third week we had 8 positive and 5 negative results (2 of the latter unsatisfactory). In the fourth week we had 3 negatives and 1 positive; in each of the fifth and sixth weeks, 2 negatives. The remaining 11 negative tests must be excluded from calculation, because the nature of the illness remained clinically uncertain to the end.

If we now take the case as the unit, irrespective of whether it was tested one or more times, we get the following percentage figures, which are shown in conjunction with those of other workers. (See Table.)

It is impossible to be exact in such statistics. The stage of the disease is often very difficult to determine. We are also well aware that it is statistically absurd to state our small series of cases in percentages; yet we have thought it justifiable to do so, in order to demonstrate at a glance the agreement of our results with those of the Danes and Americans. The fact that we have failed to isolate any *H. pertussis* after the fourth week, whereas the Danes still secured a fair percentage of successes, means very little, since we only examined a very few patients in that stage. Sauer and Hambrecht agree with us in that they failed to isolate the organism in all their 40 cases in the phase of decline. The Danish method, it seems, is to use three Petri dishes of medium for each test. We sent out two, and sometimes only one of these was used. Whenever possible, however, we repeated the test if the first result was negative, and if whooping-cough was still suspected.

Successful Isolations of H. pertussis in Cases Proving Clinically or Bacteriologically to be Whooping-cough.

Stage of illness.	A. D. G. and P. H. L. (47 cases).	Danish. (Madsen, 1924.) (914 cases.)	American. (Sauer and Hambrecht, 1930.) (200 cases.)
	per cent.

2nd week . . (Spasmodic phase)	67	57	—
3rd week . .	75	61	65 (spasmodic phase).
4th week . .	25	45	—
5th week . .	0	40	0 (phase of decline). —
6th and later .		9	

We have accepted a definite clinical diagnosis, made either before or after the bacteriological test, as sufficient proof of the identity of the illness. In five cases, however, the manifestations, though sufficient to arouse suspicion, were so atypical that clinical diagnosis was impossible. There is no doubt that these persons would have been passed by their doctors as uninfected and uninfectious had they not been bacteriologically tested. In two other cases the microbe was isolated before the development of characteristic symptoms, when the doctor was still in doubt.

The bacteriological method is therefore not only able to accelerate a diagnosis obtainable eventually by clinical methods, but also to supply one where clinical methods fail.

Determination of Infectivity.—After the sixth week from the onset the production of *H. pertussis* has practically always ceased. But if the cough, particularly of the spasmodic type, persists, the doctor may be hard put to it to advise on the duration of isolation and to decide such questions as whether the child may now go back to school. In cases such as these we recommend three tests on successive days, or two if it is certain that the illness has lasted longer than six weeks. If all the tests prove negative, the child may be considered harmless. We have carried out several examinations of this kind, to the satisfaction of doctors, parents, and school authorities.

Carriers.—There is no doubt that whooping-cough occasionally takes a mild and chronic form which would never be suspected but for some special circumstance. We isolated the microbe from an adult with no disturbance of health beyond a slightly spasmodic cough, who was living in an infected household. In Denmark the headmaster of a school was discovered to have been the cause of a succession of outbreaks

Bordet and Gengou in 1906, are well summarised by Madsen (1924), and will be mentioned again. In America Lawson and Muller (1927) and Sauer and Hambrecht (1930) have made good use of the diagnostic method, which has also proved very serviceable in France in the hands of Debré, Marie, and Pretet (1929).

When we began our work there was, so far as we know, no British publication on the subject, but shortly afterwards, as we have already mentioned, a paper was published by Sugare and Macleod (1929) who, in spite of using the sputum-plating method, which had been discarded as unsatisfactory by the Danes, isolated the bacterium in all of their five cases in the catarrhal stage. Their paper incidentally contains valuable confirmatory evidence of the invariable absence of *H. pertussis* in catarrhal conditions other than whooping-cough.

The Culture Medium.—We have used the Danish modification of the original Bordet-Gengou medium, altered in a few respects. It is made as follows:—

Potatoes are cleaned and cut into thin slices: 1 kg. of the slices with 2 litres of distilled water and 80 c.cm. of glycerin are boiled until the potatoes are soft. The water lost in the boiling is made up and the whole filtered through linen. The juice is then adjusted to pH 7·0. One part of the neutralised juice and three parts of 0·6 per cent. NaCl are mixed and distributed in flasks, 200 c.cm. in each; 4 per cent. agar is added, and the flasks are left in the cold store overnight. The medium is then autoclaved and to every 200 c.cm. are added 4·5 c.cm. of a sterile N/2 solution of lactic acid (3·72 c.cm. of ac. lact. of sp. gr., 1·21 to 100 c.cm. aq. dest.). When the flasks have been cooled to 45°–50° C., 100 c.cm. of fresh defibrinated horse's blood is added to each. The medium is then mixed well and poured into Petri dishes. It will keep good for a fortnight in the cold store.

COUGH-DROPLET METHOD.

As soon as the earliest suspicion of whooping-cough arises, the doctor obtains from the laboratory two or three Petri dishes of the special culture-medium, and instructs the parent or nurse to carry out the following directions, which are sent out with the culture-medium.

"When a *natural attack* of coughing starts, remove the glass lid of one of the dishes and, holding the dish about six inches away, allow the patient to cough for about 10–15 seconds on to the surface of the red jelly. No sputum (phlegm) must be coughed on to the surface, otherwise the plate will be spoilt. The *invisible* cough droplets are quite sufficient. Replace the lid at once. Do the same with each of the dishes provided. If the patient has no long attacks, but only a short, sharp cough occasionally, use each dish three or four times. Artificial coughs, done on purpose, are useless. Keep the dishes in a cool, dark place when not in use, and return them as soon as possible to the laboratory."

If necessary, the dishes may be sent out and returned by post. In Denmark it has been found necessary to use metal (aluminium) dishes to avoid breakage. We have found glass ones of about 2¼ in. diameter satisfactory for local use. After the speediest possible return to the laboratory, the dishes are incubated at 37° for about 72 hours, being examined each day to see that the sowing has been satisfactorily done. Any spreading colonies that may spoil the result are cut out of the medium. In about 48 hours *H. pertussis* begins to appear in the form of minute glistening colonies, but 72 hours (occasionally even four days) are required before they can be recognised with any certainty. A watchmaker's lens, which can be held in the eye, is an important aid, and we have found oblique illumination with a dark-shaded lamp preferable to daylight. The fully developed colony is about 0·5 mm. across and has a characteristic sheen, like a tiny pearl or a droplet of mercury. Zones of whitening or of clearing round the colonies, such as are sometimes described, are in our experience inconstant when the growth is young, though ageing growth always whitens the medium at a certain stage. A platinum needle easily enters the colony and picks up part of its moist substance.

IDENTIFICATION OF ORGANISM.

The typical appearance of the colonies nearly always differentiates them from those of any other organism; but sometimes, owing to the dryness of the medium or to delayed development, the colonies appear dry, whitish, and wrinkled, and considerable doubt may arise as to their identity. As a routine, therefore, when films are made from any suspicious colony, a subculture is made on fresh Bordet medium. In the case of *H. pertussis* the mass-growth is dry, roughish, and circumscribed, resembling a streak of aluminium paint. Films are stained by Gram's method, with diluted carbol-fuchsin as counterstain. *H. pertussis* appears as a small ovoid Gram-negative rod or cocco-bacillus, frequently paired, like a tiny pneumococcus. The common allegation of "bipolar staining" seems to be based on a misinterpretation of these paired forms, and it should be omitted from future descriptions of the organism. *H. influenzæ* may be distinguished from *H. pertussis* by the fact that the colonies of the former organism appear after 24 hours' incubation. They are flat and transparent, and slide over the surface of the medium when touched with a platinum needle. Subcultured on Bordet's medium they give rise to a moist, transparent, and spreading growth.

Agglutination.—Although the combination of colony appearance and cell form makes the identification of *H. pertussis* certain enough for practical purposes, we have verified all our identifications with the agglutination test.

Agglutination Test.—From the primary streak of a colony subcultures are made by smearing the growth all over the surface of one or more large dishes of Bordet's medium. After 48 hours at 37° C., the growth is scraped off and emulsified in saline solution containing 0·2 per cent. of formalin, by rubbing up in an agate mortar. After dilution to a suitable density (equal to a suspension of some 600 million per c.cm. of *Bact. typhosum*), the suspension is tested by Dreyer's method with a specific agglutinating serum, in dilutions ranging from 1 in 50 to 1 in 500 or more.

Agglutinating Serum.—Having discovered at the outset that freshly isolated cultures entirely failed to react with serums made from old stock cultures of *H. pertussis* from the National Collection of Type Cultures, we were compelled to investigate the serological structure and variability of the microbe, with results which have been published elsewhere (Leslie and Gardner, 1931).

Briefly, we found that freshly isolated cultures are all serologically alike, and we called their characteristic antigen Phase I. A distinct antigen, Phase II., occasionally replaces No. I. in the early stages of laboratory life. These two phases are toxic to animals, and represent the smooth state of the microbe. Cultures grown and stored on Bordet's medium may preserve their original antigenic constitution for months, but directly they become accustomed to grow on heated blood, egg, or meat-infusion media, the antigen of Phase I. (or II.) disappears, and an entirely different one (III.) takes its place. In old stocks a further change to Phase IV., with a final antigenic alteration, often occurs. These last two phases are non-toxic to guinea-pigs, and represent the rough state. The fundamental features of this change were described long ago by Bordet and his collaborators, but it is only in the light of recently-acquired knowledge of bacterial variation that we have begun to understand it.

TREATMENT OF ACUTE LOBAR PNEUMONIA BY ARTIFICIAL PNEUMOTHORAX.

BY J. J. COGHLAN, M.R.C.S. ENG.,
LATE ASSISTANT MEDICAL OFFICER, ST. OLAVE'S HOSPITAL, LONDON, S.E.

DURING an investigation into lobar pneumonia it was discovered that the induction of artificial pneumothorax had a favourable influence on the progress of this disease. In view of the arrival of winter, with its attendant respiratory infections, the following cases are reported in order to give an idea of the results which may be obtained, and to allow others to test the method.

Although a full account of the theory and rationale of this treatment will be published later, it may be briefly stated here that the induction of artificial pneumothorax on the affected side, according to the technique described, has the advantage that it (1) separates the inflamed pleural surfaces, relieves pain, and allows of easy respiration; (2) puts the inflamed lung at rest; and (3) limits the flow of blood through the pneumonic lung, thereby diminishing anoxæmia, and interfering with the passage of toxins into the general circulation.

In observing the results it is well to chart respiration-rate as well as temperature because, as will be seen, these curves are of great value in following the course of the disease, and in assessing the effects of treatment. In fact, they form a very accurate guide on which to base treatment.

Case Records.

The following are brief reports of six cases.

CASE 1.—Male, aged 20. Admitted to hospital at midnight on June 21st, 1931. Right lobar pneumonia, fourth day of disease.

On admission the temperature, pulse-rate, and respiration-rate readings were: T. 102° F., P. 96, R. 32. These figures rose till, at 2 P.M. on June 22nd, they stood at T. 102·4°, P. 124, R. 46. Examination showed solidification of right middle and lower lobes. At 2 P.M. artificial pneumothorax was induced on affected side. In spite of preliminary medication with morph. gr. ¼, the pleura was found to be intensely hyperæsthetic—a feature common to all the cases dealt with—rendering necessary very complete local anæsthesia before the patient would tolerate the passage of the artificial pneumothorax needle.

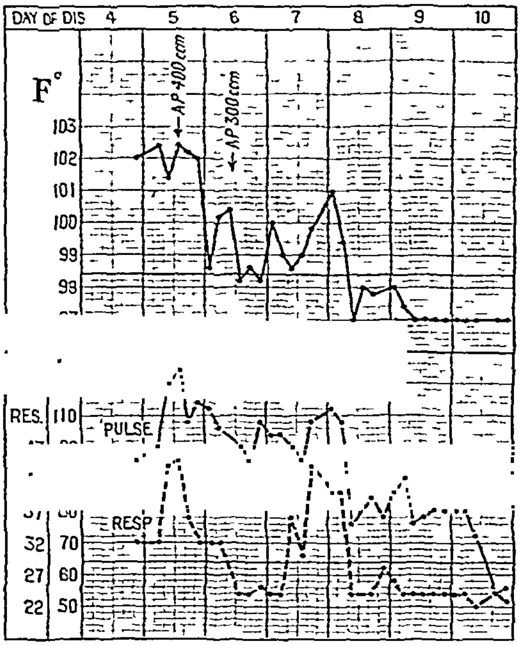
On entering the pleural cavity, a second feature common to all the cases was encountered—namely, the extremely wide and irregular variation of the intrapleural pressure as measured on the manometer, −40 to +40 being quite a normal swing. These pressures were not perceptibly altered as the air entered and, consequently, the manometer could not be used as a gauge to check the filling in these cases, as it can in pulmonary tuberculosis. There was no difficulty in inducing the pneumothorax; the air, which was admitted very slowly, entered easily, and the pneumonic lung fell away from the chest wall and collapsed quite readily; 400 c.cm. of air were used on the first fill. The therapeutic results were immediate and obvious; the patient, who until then had had the usual hot, dry skin of pneumonia, began to perspire freely; cyanosis and dyspnœa were both diminished, thoracic pain disappeared, and the patient "felt much better." Profuse perspiration continued, and by 2 A.M. on June 23rd the chart readings had fallen to T. 98 6°, P. 112, R. 32. The patient was very comfortable and looked as if he had just negotiated the crisis.

From this point the picture changed again. Perspiration ceased, the skin becoming hot and dry, and the temperature rose steadily, reaching T. 100·4°, with P. 106, R. 32, at 10 A.M. on the 23rd. As it was obvious that the patient was rapidly reverting to a condition of acute pneumonia, the pleura was again punctured. It was now discovered (again a feature common to all the cases) that the absorption-rate of the inflamed pleura was abnormally high: the 400 c.cm. of air admitted 20 hours previously had been completely absorbed, and the lung was again in contact with the chest wall. 300 c.cm. of air were admitted, and the procedure was followed at once by profuse perspiration and clinical improvement. In four hours, at 2 P.M., the chart readings were T. 98·2°, P. 100, R. 24. From this point, although there were two transient temperature rises, to 100° at 2 A.M. on June 24th and to 101° at 2 A.M. on the 25th, as the temperature fell away immediately afterwards of its own accord to normal in each case, and as the patient was obviously well clinically, no more air was admitted.

From 2 A.M. on June 25th the chart readings steadied at an average value of T. 97°, P. 80, R. 22; the patient made an uneventful convalescence, left the hospital in good health, and was seen, quite well, three months later on return from a convalescent home.

A radiogram of the thorax taken on June 30th, five days after the final settling of temperature, shows: (*a*) a small residual collapse in the apical region; (*b*) resolution of the right lung nearly complete; (*c*) no evidence of fluid effusion.

FIG. 1 (Case 1).



This rapid resolution appeared to be a feature of all the cases.

CASE 2.—Female, aged 9. Admitted 8.30 P.M. June 20th. Right lobar pneumonia, second day of disease. On admission, chart readings were T. 103°, P. 128, R. 30. Right lung solid from base to apex.

As will be seen from Fig. 2, during the first three days in hospital this child ran an evening temperature of 103° to 104°. By midday on the fourth day she was semi-comatose and was not expected to survive the night. Although it had originally been intended to exclude children, this child was so obviously dying that, in view of the encouraging results already obtained, artificial pneumothorax was induced at 5.30 on the 23rd, 150 c.cm. of air being admitted. The same phenomenon of wide variation of intrapleural pressure was noted as in the previous case, and the lung collapsed quite as readily. The child was too ill to object in any way to the operation. Profuse perspiration set in at once; at 6 P.M. the chart readings had fallen to T. 100 2°, P. 120, R. 28; at 10 P.M. the temperature was normal. The child passed a comfortable night, the chart readings next day being:—

	Temperature.	Pulse.	Respiration.
6 A.M.	101·8°	104	24
10 A.M.	96·8°	100	19
2 P.M.	100·2°	106	22
6 P.M.	97°	96	28

Since the clinical improvement, as can be gathered from the above figures, was very marked, and as nothing was then known of the rapid absorption of air in these cases, no further refill was given on this day. Next morning the pneumonia was returning, the 6 A.M. chart readings being T. 102°, P. 112, R. 32, and by evening was fully re-established, of the disease. It seems, however, that such cases are rare, and that healthy carriers play a minor part in the spread of the illness. It is in the undiagnosed early catarrhal state that most of the damage is done.

ADVANTAGES AND DISADVANTAGES OF THE TEST.

Advantages.—(1) Unlike many laboratory tests, such as the Widal and Wassermann reactions, it is at its best at the very beginning of the illness, before symptomatic diagnosis is possible. (2) No drawing of blood or other painful or time-consuming operations are necessary. (3) When positive it gives complete certainty.

Disadvantages.—(1) It takes three days. Meanwhile the diagnosis may sometimes be made on clinical grounds. (2) Single tests fail in about 25 per cent. of cases owing to faulty management by mother or nurse. (But repetitions will usually succeed.) (3) The culture medium deteriorates rather quickly, and must be made every fortnight. (4) A horse and a *refrigorator are necessary for large-scale work.* [The former may, however, be borrowed for an hour fortnightly at a small fee. Small batches of medium can be made with human or rabbit blood.]

In spite of these disadvantages we have found the test to be of great assistance to doctors; and when, in the future, the State becomes interested in the not inconsiderable number of babies' lives and the innumerable hours of school lost through this disease the aid of bacteriology will necessarily be called on to the fullest degree. Meanwhile, it would prove a boon to a large and increasing number of progressive practitioners if bacteriologists at central laboratories would master the method and make it available for general use. We are convinced that public health authorities would find it well worth while to make use of, and if necessary to pay for such a ready help towards the early diagnosis and consequent limitation of school epidemics.

Use of Specific Vaccines in Prevention and Cure.

It is difficult to give a useful opinion on the value of vaccines in the treatment of whooping-cough, for there are no data suitable for statistical analysis. But if there is a specific element in the vaccine treatment of infectious diseases in general; if, that is to say, the acceleration of the healing processes of nature, which often, though irregularly, follows the injection of vaccines, is not entirely due to non-specific "protein shock," then we can predict that the results in whooping-cough will be greatly improved by using a vaccine that contains the chief antigen of the virulent, parasitic phase of *H. pertussis*. In England and the U.S.A. the vaccines in general use have usually been innocent of this necessary ingredient (Leslie and Gardner, 1931). We are in a position to state that the vaccine now being produced by the inoculation department at St. Mary's Hospital, and sold by Parke, Davis and Co., is of the quality desired.

Of much greater public importance is the problem of raising individual and herd immunity against *H. pertussis*. A review of the work done on these lines has been given by Madsen (1924). Most of the reports are strongly favourable, and in discussing the Danish work Madsen says that "although no absolutely sure prophylactic effect has been obtained . . . there is no doubt that infection is lighter among the vaccinated than among the non-vaccinated." Since we know that the cultures from which the vaccines are made at the State Serum Institute in Copenhagen are propagated on fresh blood medium, on which the original toxic and immunity-producing component of the organism is preserved, the Danish experiences are especially deserving of respect. In a large epidemic in the Faroe Islands in 1923 the mortality *among vaccinated patients was only one-twelfth* of that among the non-vaccinated. It seems that the duration of the immunity is short, and that its maximum effect is within a week or so of the final injection. Madsen recommends three subcutaneous or intramuscular doses of 0·5 c.cm., 0·7 c.cm., and 1·0 c.cm. of a suspension in saline solution + 0·5 per cent. phenol of about 10,000,000 bacteria to the c.cm. In our experiments on animals (loc. cit.) we made use of the well-known detoxicating effect of formalin by killing our vaccines with 0·2 per cent. of that substance and storing in the cold for at least a week before use. The highly poisonous endotoxin of the bacillus is well neutralised in this way.

Theissier, Reilly, Rivalier, and Cambassédes (1929), working with endotoxin extracted from the bacilli *and treated with 3 per cent. formalin,* were *unable* to produce detectable protective substances in the blood of human beings, or any curative effect in the established disease. But their formalised endotoxin, though harmless and highly protective to animals, produced such a sharp reaction in the human subject that only very small doses could be given (one wonders whether the very high concentration of formalin may have been to blame). With whole bacilli treated with formalin no protection of animals could be effected.

Finally, it may be mentioned that complement-fixing antibodies are produced in normal human beings by the injection of vaccines of *H. pertussis* (Kristensen, quoted by Madsen), just as they are in infected subjects by the living microbe.

Thus the evidence on the value of preventive vaccination is conflicting, but the Danish experiences are promising enough to make a more extended trial of the method desirable.

Summary.

The bacteriological method of diagnosis of whooping-cough and the results of more than 100 tests of suspected persons, compared with the experiences of foreign workers, show that in the early stages of the disease at least three out of four cases can be detected by a single examination. The fourth eludes detection only because of human fallibility. Reasons are given for the final acceptance of *Hæmophilus pertussis* as the cause of whooping-cough, and the desirability of using antigenically efficient cultures in the manufacture of vaccines is emphasised.

Our thanks are due to the medical practitioners who have supplied us with material and to the Medical Research Council, who have given financial *assistance.*

can be attributed to error of judgment in a difficult situation and lack of knowledge of the technique, owing to inexperience, rather than to a defect in the method of treatment itself, for it was obvious that the pneumonic process was as well controlled by the artificial pneumothorax in this instance as in the previous cases. Unfortunately no autopsy could be obtained.

CASE 5.—Male, aged 25. Admitted 6 P.M. on Oct. 3rd. Solidification of right lower lobe, first day of disease. On admission the chart readings were T. 101°, P. 128, R. 38.

The patient had had several previous attacks of pneumonia, and came into hospital on the first day of the disease. He was kept under observation till 6 P.M. on the 5th, by which time the diagnosis was fully confirmed, and solidification of the right lower and mid-zones well established. Chart readings T. 105°, P. 124, R 32.

This case is of interest as being the one case of the series in which the pneumonia was not cured by artificial pneumothorax, and, consequently, furnishes data which could not be obtained from the others.

Artificial pneumothorax was induced at 6 P.M. on the 5th. The patient was of a highly nervous, resistive type, and groaned and moved violently during the operation, and owing to non-cooperation on his part, it was only possible to admit 250 c cm of air. Crisis was at once established, and the patient perspired well In two hours' time the chart readings had fallen to T. 99 8°, P. 100, R. 22, and in four hours to T. 98°, P. 88, R. 20. The small quantity of air admitted was rapidly absorbed, and by 2 P.M. next day the figures were T. 104·4°, P. 112, R. 28. Here another attempt at induction was made. The patient, however, was so antagonistic that after only 100 c.cm. of air, at most, had entered, he displaced the needle from the pleural cavity by his violent movements, and from this time on refused any further treatment. As the result of this small refill the chart readings again fell steadily to T. 100 4°, P. 100, R. 28, which figures were reached at 10 o'clock the same evening. The air was soon absorbed, the pneumonia became fully re established, and remained so for seven full days, when the normal crisis occurred

FIG. 4 (Case 5).

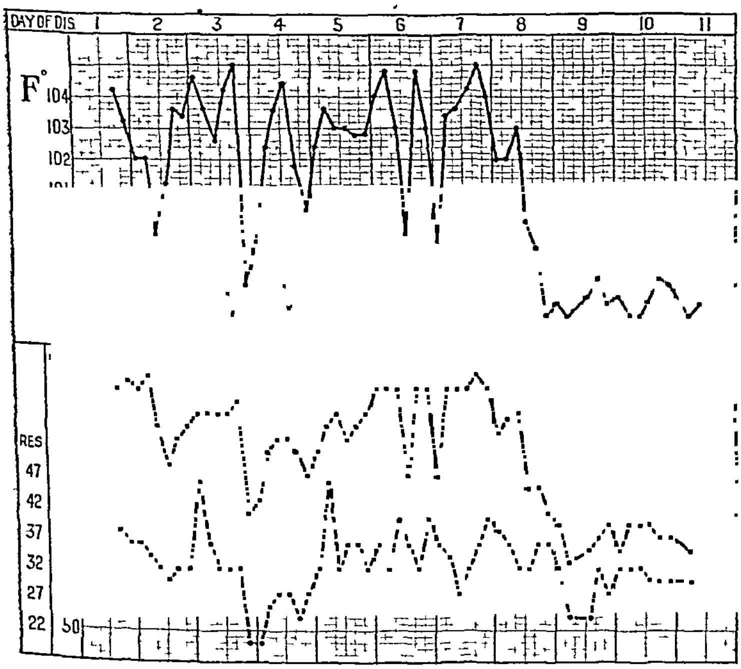

FIG. 5 (Case 6).

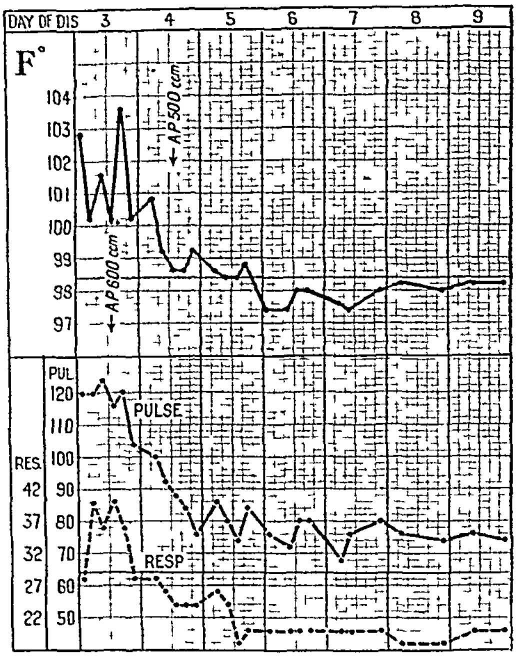

This case is instructive because it fully meets the objection that the crises produced in the previous cases were not due to the artificial pneumothorax, but were merely accidental coincidences of the normal crisis with the induction. In this case a crisis was produced on the third day of the disease; as soon as the air was absorbed the disease returned, and the natural crisis did not occur for a further seven days. This, taken in conjunction with the previous results, makes it impossible to come to any other conclusion than that artificial pneumothorax induces a crisis, and that this is due to the presence of air in the pleural cavity and ceases when the air is absorbed.

CASE 6—Male, aged 23. Admitted 2 A.M. on Nov. 6th. Right lobar pneumonia, third day of disease.

On admission, chart readings were T. 102 8°, P. 120, R. 23. Examination showed solidification of right lower and middle lobes.

This was the most successful case of the series from the clinical standpoint, for by now it was fairly clear what the correct technique should be, and the necessity for two fills at short intervals was fully recognised. As a consequence, the patient received 600 c cm. at 2 P.M. on the 6th and 500 c.cm. at 2 P.M. on the 7th. At 2 P.M. on the 7th, before the second fill was given, the chart readings were T. 98 6°, P. 88, R. 24, and from this point convalescence was uneventful. On giving the second fill, it was again noticed that almost all the air had been absorbed, and three radiograms showed that absorption of the pneumothorax was completed in less than a week, and that resolution occurred as rapidly as before.

In order to establish as thoroughly as possible the identity of the artificial crisis with the natural one, estimate was made in this case of the urinary chlorides and the white blood count before and after the defervescence produced by the pneumothorax.

Nov. 6th. Urinary chlorides—400 mg. per cent. W.B C. 19,200.

Nov. 7th. Urinary chlorides—640 mg. per cent. W.B.C. 14,200.

the 6 P.M. chart readings being T. 103·6°, P. 134, R. 40. A second fill of 100 c.cm. was accordingly given.

The crisis again set in rapidly: at 6 A.M. next day the chart readings had fallen to T. 101°, P. 110, R. 34. By evening they were T. 97·6°, P. 116, R. 32, and by next morning T. 97°, P. 80, R. 28. From this point convalescence was uneventful and the lung resolved as rapidly as in the previous case. The child went to a convalescent home in good health, and returned some months later, perfectly well.

CASE 3.—Male, aged 32. Admitted at 6 P.M. on Sept. 15th. Left lobar pneumonia, third day of disease.

On admission the chart readings were T. 101·6°, P. 112, R. 32. Examination showed solidification of the left lower lobe.

Since the question of the best technique to be adopted both as to size and frequency of refills could only be solved by experiment, this patient was only given 250 c.cm. at his first fill, which took place at 7 P.M. The skin immediately became moist, and the patient passed a very comfortable night, sleeping most of the time, but the amount of perspiration was slight as compared with the two previous cases. At 6 next morning the chart readings were T. 100°, P. 100, R. 32, which rose to T. 101·2°, P. 104, R. 36 at 10 A.M. A second refill of 200 c.cm. was now given. Perspiration set in freely, the temperature falling by 12 noon to 99·8°. It rose again at 6 P.M. to 101·2°, but as the patient was perspiring freely and feeling well, nothing further was done, and the rates steadily fell until by 6 A.M. the figures were T. 97·6°, P. 100, R. 32. During this day the chart readings rose suddenly at 12 noon to T. 100·8°, P. 104, R. 32, but immediately fell away, and by 4 P.M. were T. 98·4°, P. 86, R. 32, from which point it remained normal. The fills in this patient (250 and 200 c.cm.) were evidently too small to control the pneumonic process properly.

A radiogram taken on Sept. 21st, six days after admission, showed a small residual pneumothorax in the left basal region, and resolution of the left lower lobe advancing nicely. The right lung, however, showed extensive mottling and increase of root shadows (? old tuberculosis), and the patient gave a history of pneumonia in childhood. Old lesions may have contributed, along with the small fills given, to the comparative slowness of the response to treatment in this case, for on three separate occasions during the next month, while under observation in the ward, this patient showed an evening temperature of 99°, following exertion during the day. However, nothing could be detected clinically, the temperature was normal during the rest of his stay (although he was up all day), and he was discharged to a convalescent home, apparently well.

FIG 2 (Case 2).

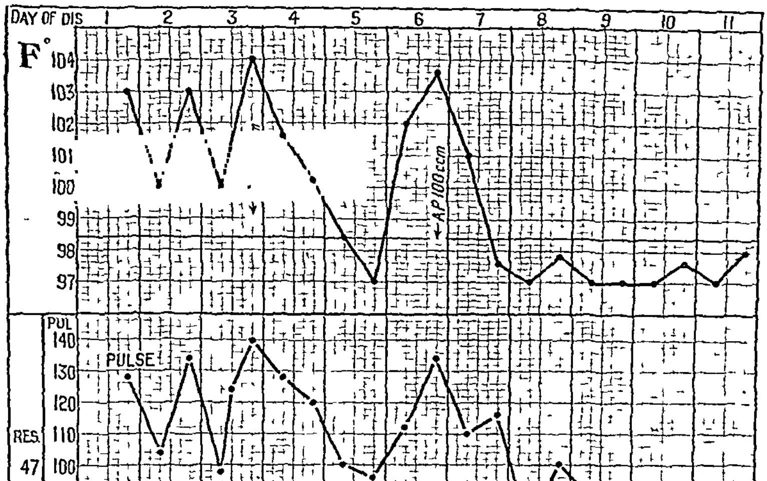

FIG. 3 (Case 3).

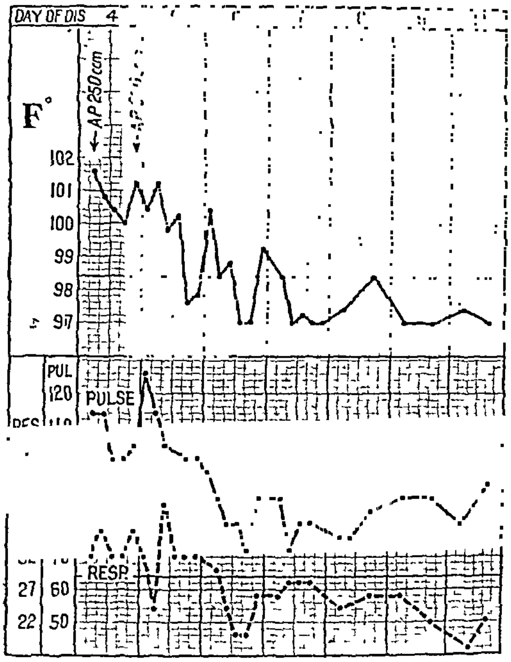


Radiography on Dec. 10th, however, showed very obvious fibrotic changes in the right lung, and as there seemed a definite increase in the shadows at the right base, the sputum was again tested, and two consecutive specimens proved positive for tubercle bacilli. The patient protested that he felt perfectly fit, and nothing could be detected by the stethoscope.

CASE 4.—Male, aged 55. Admitted 12.30 P.M., Sept. 18th. This patient, an elderly, poorly nourished man, had been ill at home for several days. On admission his condition was very bad, the chart readings being T. 99·8°, P. 132, R. 36. He was intensely cyanosed, the pulse was feeble, and the cardiac condition very poor. There was extensive solidification of the left middle and basal zones. In addition, there was a past history of chronic bronchitis, and the right lung showed evidence of emphysema and basal congestion.

A difficult point at once came up for decision. Granting the pneumonic process could be controlled by pneumothorax, would it be better for the damaged heart to aim at an immediate and complete crisis by a large fill, thereby bringing the toxic process to a stop, and risking the strain on the right ventricle caused by the resulting embarrassment of the pulmonary circulation, or to aim at a fall by lysis by a series of very small fills, thereby avoiding the immediate strain but exposing the heart to a further 36–48 hours of toxæmia? The first course was ultimately adopted. The patient was given insulin and glucose with the idea of improving the nutritive reserves of the myocardium by the deposition of glycogen, and after allowing half an hour for this to be absorbed, was prepared by morphine and strychnine, and 750 c.cm. of air was admitted to the left pleural cavity. A very violent crisis set in; the patient perspired profusely, the cyanosis became markedly diminished, and the patient felt much better. The improvement continued till 10 P.M., the temperature then being 99° and the pulse 100. Here, however, the pulse began to rise, and signs of failure of the right ventricle appeared. The patient was given the usual cardiac stimulants and revived temporarily, but the right ventricle failure increased progressively, acute œdema of the contra-lateral lung appeared at 4 P.M., and the patient died at 6 A.M.

This case was the only fatal one of the series. It air, run in very slowly during the negative phase of the pressure swing cycle, and with the needle clipped off during the high positive phases. (5) A second fill 12 hours later of 300–500 c.cm. of air. (6) If the pneumonic process is not completely controlled, a third fill of 100–150 c.cm. of air may be given in another 12 or 18 hours. (7) Simultaneous exhibition of a suitable diaphoretic and of Felton's serum in appropriate cases at the discretion of the operator. (8) Owing to the very profuse perspiration, the comfort of the patient is much enhanced by warm sponging p.r.n. and nursing between blankets. (9) In cases where it is deemed inadvisable to provoke defervescence by crisis, and a gradual fall by lysis is aimed at, three fills of 100–150 c.cm. at intervals of six hours might be given and further treatment judged by results.

No special points with regard to *after-treatment* were noted. Patients 1 and 3 were given blow-bottles with the idea of promoting re-expansion of the lung and absorption of any residual air, but this did not seem to be really necessary or to be of any particular advantage.

Finally, lobar pneumonia is emphatically not the disease on which to gain a knowledge of the technique of artificial pneumothorax.

I am indebted to Dr. R. Kelson Ford, medical superintendent of St. Olave's Hospital, for permission to publish these cases, and I also wish to express my thanks to my colleague, Dr. M. S. Purvis, for kindly undertaking the treatment and care of these patients in his wards.

THE INJECTION TREATMENT OF HÆMORRHOIDS.

By Peter G. McEvedy, F.R.C.S. Eng.,
HON. SURGEON, ANCOATS HOSPITAL, WARRINGTON INFIRMARY, AND STRETFORD MEMORIAL HOSPITAL.

Because of man's upright position and mode of life under modern civilised conditions, his venous system is subject to much stress, and it is not surprising that disease of this system is extremely common. The modern treatment of varicose veins and of piles has made their prevalence more apparent. There is now no doubt that the injection treatment of piles has largely replaced the operative treatment. There is also no doubt that many with insufficient knowledge and very inadequate equipment are practising this method with a certain amount of success. Their complications are many, their results are only temporary, and they are bringing discredit on a very efficient form of treatment.

For all practical purposes uncomplicated piles produce few symptoms. Bleeding is the commonest, and usually the first; it occurs during defæcation, and the blood is bright red. The second commonest symptom is prolapse. In its early stages prolapse may occur during defæcation, and either reduces spontaneously or is easily reduced by pressure. With the continuation of prolapse, the external sphincter loses its tone and protrusion of the piles is effected with less and less force until a stage is reached when the piles prolapse during slight exertion. Finally they may remain chronically prolapsed. As the prolapse becomes more marked the mucous membrane becomes thickened and the tendency to bleed becomes less. The third symptom is the discharge of mucus. This is a late symptom, and is the result of frequent or chronic prolapse. Piles may cause a feeling of fullness in the rectum, but pain is not a symptom of uncomplicated piles, except while they are prolapsed.

Three things must be done before arriving at a diagnosis of piles. First, the anal region must be inspected; secondly, the rectum must be examined with the finger; thirdly, the rectum must be inspected with an efficient proctoscope. In certain cases this must be followed by sigmoidoscopy and X ray examination of the colon before a complete diagnosis can be made.

Treatment.

Before advising treatment for piles it is necessary to make a general examination of the patient. Faults in living and in diet can be corrected, and those cases where the piles are due to cardiac or hepatic conditions or are associated with abdominal tumours or prolapse of the uterus can be discovered. Unless the underlying cause in these cases is recognised at the beginning, much disappointment will follow any form of treatment. Having excluded the cases that have an obvious general or local cause, it is necessary to decide the stage of development the piles have reached, and also if there are any complications. As a rule, complications must be treated first.

OPERATIVE TREATMENT.

In long-standing cases, especially where attacks of thrombosis have occurred, the piles become fibrotic or polypoid. The more fibrotic the piles, the less suitable they are for injection treatment. Polypoid piles can be treated only by operation. Where there is a single large fibroid polyp, and the remaining piles are suitable for treatment by injections, the polyp can easily be removed under local anæsthesia and the injections commenced a week later. External piles can be treated only by operation. The proportion of patients suffering from piles that will need operative treatment will depend on the surgeon's experience with the injection treatment. With a wide knowledge of modern injection methods 80 per cent. of cases can be treated in this way.

INJECTION TREATMENT.

The treatment is ambulatory. It requires much more practice, time, and patience than other forms of injection treatment. Unless the necessary instruments are available, and are in good working order, the treatment becomes farcical.

The following *instruments* are necessary:—

1. A suitable *rectal speculum*. Since good illumination is essential, a speculum fitted with a light should be considered. The Cameron lighted rectal instrument and an illuminated rectal speculum made for me by Down Bros. are two that meet the requirements.

2. A *graduated syringe*. The Morley type of syringe is very satisfactory.

3. Suitable *needles*. The needles can be a great source of annoyance, and, owing to the effect of the solution used, show a tendency to become blocked. Down Bros. make for me a straight needle, five and a half inches in length, with wide bore as far as the terminal portion. The terminal portion is of the usual bore, made of nickel, and fitted with a guard. There is a bayonet catch on the syringe to prevent the needles slipping off. When the needles become blocked, it is not sufficient to pass a stylette; this merely presses the particles to one side and the needle quickly becomes blocked again. Screw the guard on as far as possible, reverse the needle, insert the nickel or gold portion in the nozzle of the syringe, and forcibly squirt water from the syringe. Some

There was thus a rise in the urinary chlorides of 60 per cent. and a fall in the leucocyte count of over 25 per cent. in less than 24 hours after the induction of the pneumothorax, a fact very difficult to explain if the mechanism of the defervescence due to artificial pneumothorax and the natural crises were not essentially similar phenomena.

A point of interest is that the radiograms of these cases showed that acute pneumonia possesses the typical distribution of a disease spread by the bronchi with the usual predilection for the right middle zone. This rules out the suggestion that the disease is a septicæmia with local manifestations, or that the lung is infected from the blood stream.

Practical Considerations.

From the experience gained from these six cases, it is possible to draw certain conclusions as to the therapeutic results obtainable, and also as to the technique to be adopted to get the best results. These, of course, are only advanced tentatively at present.

The first and most obvious clinical result was that the induction of artificial pneumothorax initiated a series of events almost indistinguishable from the crisis which normally occurs in this disease. It is true that there were certain minor variations noted, but these do not affect the practical result.

The second conclusion is that this control of the pneumonic process is at first only temporary, persisting merely as long as air remains in the pleural cavity. Since the absorptive capacity of the pleura in this disease is abnormally high—a factor which had not been suspected at the beginning of these investigations—the time taken to absorb the air is a matter of hours only, after which the pneumonic process becomes re-established at its original level. By adequate refills, however, this return of the disease can be forestalled, and when the artificial pneumothorax control has been maintained for a sufficient length of time (48 hours appears to be approximately correct) the pathological process is definitely brought to an end, the air can be absorbed without any tendency to relapse, and convalescence proceeds normally. Resolution in the successful cases occurred more rapidly than usual, probably because, as the time of the disease was shortened, there was less damage done to the lungs and less exudate formed in the alveoli than if the pneumonia had been allowed to run its full course to a natural crisis.

A striking feature of all the cases was the rapidity of the onset of the artificial crisis; profuse perspiration set in almost as the pneumothorax needle was withdrawn, and cyanosis and dyspnœa were relieved in about 15 to 30 minutes at most, causing corresponding subjective improvement. The fall of temperature was well established in two to three hours, and the patient lost that appearance of acute distress characteristic of pneumonia.

POSSIBLE DANGERS.

Certain practical dangers had been suggested, some serious, others more or less fanciful. The serious ones were :—

1. *Pyopneumothorax.*—Seeing that empyema is a fairly common complication of pneumonia and that pleural effusion is almost equally common in artificial pneumothorax, this possibility was not to be lightly disregarded. To minimise the risk as far as possible, the very strictest precautions were taken with the aseptic technique during induction, for mixed infections, always dangerous, might in these cases have proved disastrous. Similarly, the greatest care was taken to avoid unnecessary injury of the pleura, and the points for the various refills were spaced well apart. For the rest, the very closest watch was kept on the cases, clinically and radiologically, for any sign of pleural effusion, and none was discovered. There is no evidence, therefore, that the induction of artificial pneumothorax tends to increase the liability to empyema formation in pneumonia, when undertaken with proper precautions.

2. *Cardiac collapse* again is a recognised danger in the crisis, for it occurs normally, and was, therefore, to be anticipated here. In favour of the patient submitted to artificial pneumothorax treatment was the fact that the crisis was induced several days before it would ordinarily have occurred, and, presumably, the heart was better prepared to meet the process. On the other hand, the artificial crisis was at least as violent as the natural one. In young, and otherwise healthy, adults, the cardiac condition can be largely disregarded, but in elderly and debilitated patients it becomes a subject of primary importance, especially when treatment by artificial pneumothorax is adopted. The extent and severity of the artificial crisis depend directly on the volume of air admitted, and are thus largely within the control of the operator. In elderly patients especially, and to a less extent in all cases, it is suggested that reliance should not be placed solely on the artificial pneumothorax, but that full use should be made of other therapeutic measures.

A suggested technique is that a full crisis should be avoided and a series of small minimal fills given, just enough to initiate perspiration, and that the perspiration should then be encouraged by the use of a standard diaphoretic, such as aspirin, phenacetin, or Dover's powder. By this means the temperature will be lowered in a sequence of steps, as it were by lysis, with the minimum of strain on the pulmonary circulation, and, at the same time, a progressive detoxication will be accomplished. Advantage could also be taken in Group I. infections of the antitoxic effect of Felton's serum, and, at the same time, adequate support should be given to the heart, *sec. art.* Venesection should be of great use in this connexion. Further experience will be necessary, however, before the best procedure for these cases can be properly established.

Among the more fanciful dangers suggested were death by pleural shock, pulmonary abscess and gangrene, pulmonary embolus, and pneumococcal septicæmia. All that can be said is that these did not occur, and that there seems to be no very valid reason why they should.

It is a matter of indifference where the air is admitted; at first it was admitted over the middle of the consolidated area with the idea that any freshly formed fibrinous adhesions which might exist would be broken down by the passage of air between the solid lung and the pleura. There was, however, no evidence of any such state of affairs; the air entered quite easily, and the lung readily fell away from the chest wall. Touching the lung with the pneumothorax needle provoked no response from the patient, so the visceral pleura is evidently insensitive, even when acutely inflamed—in a marked contrast to the parietal pleura, which was acutely painful. An attempt to avoid this by injecting well away from the pneumonic area over healthy lung was not successful, the pleura being equally hyperæsthetic in this locality.

SUGGESTED PROCEDURE.

The following routine is proposed for average cases :—

(1) Preliminary medication one hour before induction with morphine gr. ¼. (2) Thorough local anæsthesia with novocain down to and including the parietal pleura. (3) Very thorough asepsis during induction. (4) A preliminary fill of 400–600 c.cm. of

3. *Pain.*—After the injections there is frequently a feeling of fullness in the rectum for a few hours, especially towards the end of the treatment Occasionally there is actual pain, and this may last as long as 24 hours. Severe pain means one of the following complications:—

(*a*) *Fissure.*—This develops in about 2 per cent. of cases and is due to the use of a speculum and the effect of the carbolic. It is more likely to occur if any leakage of the solution is not swabbed out with cotton-wool. The fissure must be treated before continuing with the injections.

(*b*) *Thrombosis or strangulation of a pile.*—This may follow if a pile prolapses after an injection and is not promptly replaced.

(*c*) *Thrombosed external pile.*—This may be the cause of the pain, but is probably not more likely to happen while the piles are being injected than at other times.

(*d*) *Necrosis.*—If the injection has been given into the mucous membrane, and this becomes white over an area of half an inch or more, necrosis will follow, and result in a superficial ulcer. There may be slight pain for a few days. Such ulcers heal quickly. If the injection has been given deeply into the pile and much pressure has been necessary, showing that diffusion has been limited by fibrosis, then deep necrosis may follow and be accompanied by pain.

4. *Hæmorrhage.*—(*a*) *Primary:* Appreciable bleeding may follow immediately the needle is removed. Without treatment, this may continue for several hours. If there is any bleeding or return of the fluid on withdrawing the needle, immediately apply a cotton-wool swab and hold it firmly in place until all bleeding has stopped. (*b*) *Secondary:* Slight secondary hæmorrhage may occur from superficial ulcers. Marked secondary hæmorrhage only occurs after deep necrosis. It is extremely rare after the modern method. I had one case when using 20 per cent. carbolic in glycerin and water.

5. *Urinary affections.*—There have been rare cases where the patient has had painful and frequent micturition after the injection, or there has been blood and albumin in the urine. These conditions have probably been due to an anterior injection given too deeply or to the effects of carbolic on the kidneys.

6. *Ischio-rectal abscess.*—This occurred twice in cases treated at hospital. It is probably caused by faulty sterilisation of the needles. In each case it was necessary to incise and drain the abscess.

Recurrence.—The treatment by submucous injections has not been in use long enough for me to state the percentage of recurrence. Treating 80 per cent. of cases by injections will give at least 10 per cent. of recurrences within two or three years. Many of these can again be made symptom-free by a further course of injections.

Injections do not interfere with a subsequent operation. In severe cases, where treatment has failed after several injections, the operation has proved easy, the bleeding has been remarkably little, and the final results excellent. The injection treatment of internal piles gives late results that are inferior to operative treatment. In spite of this, the majority of patients choose the injection method because it is ambulatory, is free from serious complication, is practically painless, and, on the whole, gives good results.

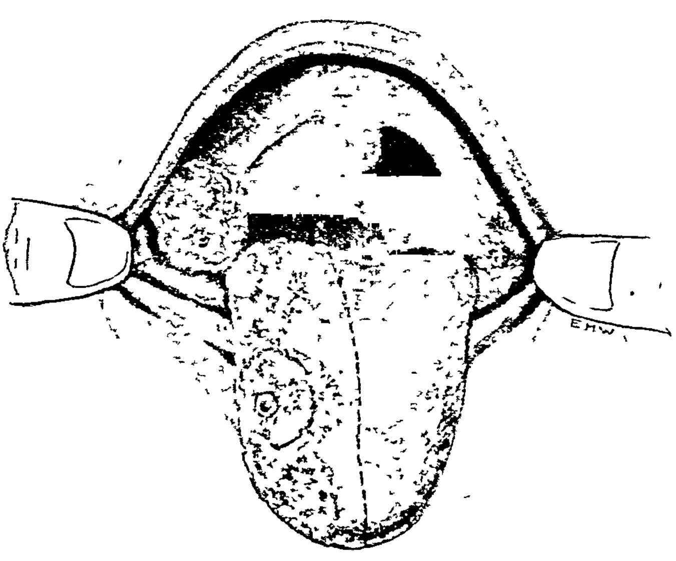
CLINICAL AND LABORATORY NOTES

A CASE OF PRIMARY CARCINOMA

DEVELOPING, AT INTERVALS, IN THREE DIFFERENT PARTS OF THE BUCCAL CAVITY.

BY LORD MOYNIHAN,
PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

IN October, 1928, I removed the right half of the tongue of a man, aged 48, for "carcinoma in an early stage." There was a small hard sessile papillomatous tumour which was slightly ulcerated; it was surrounded by patches of old leukoplakia. Subsequently Crile's operation for removal of the glands of the neck was performed on the right side. In May, 1931, the patient returned with a large carcinomatous ulcer on the right anterior pillar of the fauces. This was treated with radium. There was no sign of disease in any other part of the buccal cavity. In October, 1931, the patient again returned, with a small wart on the inside of the left cheek; its base was hard. I removed it. The pathological examination showed "early carcinoma." The fauces and the remainder of the tongue showed no evidence of disease.



Composite drawing showing the three growths, which appeared separately.

All these three growths were discrete; there was no visible connexion between any two of them. The pathological reports of Prof. M. J. Stewart showed that each was malignant. In cases of early malignant disease of the tongue, easily accessible, I confess to a preference for surgery over treatment by radium. I have performed many operations for removal of half the tongue for carcinoma, and have never yet seen an example of local recurrence. I must state this explicitly because recently in consultation in London with one who is expert in the treatment of cancer with radium we differed as to the treatment of a case of very early carcinoma at the side of the tongue. My colleague's objection to operation was "the frequency of local recurrence after removal." As I have never met with an instance of this disaster I remain of the opinion that in of the water goes through the needle in the reverse direction and displaces the particles.

4. A pair of long Spencer-Wells *forceps*, to be used for swabbing.

5. A small bowl with cotton-wool swabs. The cotton-wool is made into balls the size of a walnut before being sterilised.

6. A bowl for used swabs.

7. A small enamel bowl or glass beaker into which the solution is poured so that it can be drawn up into the syringe.

8. A suitable lubricant such as KY jelly.

All instruments are sterilised by boiling before being used.

Solution.—The solution used is 5 per cent. carbolic in *Oleum arachis.* A small quantity of the oil is warmed, and the carbolic crystals are added. The crystals readily dissolve; the rest of the oil is then added. I have given up adding menthol to the solution. Almond oil may be used, but does not seem to keep well, and seems more likely than the other oils to produce symptoms. *Oleum nucis* (Wesson process) is good, but becomes thick and cloudy in cold weather and must be warmed before being used. The solution must not come in contact with water in the beaker, syringe, or needles.

Preparation of the patient.—If the patient is in the habit of taking liquid paraffin, this is stopped for two days before the injections. Aperients are not given, but it is best if the bowels open naturally before the injections are given. The patient lies in the left lateral position well to the side of the couch, with the thighs fully flexed and the knees slightly flexed. If, on inserting the speculum, the rectum contains liquid fæces these can be partly removed by wool swabs. A swab or two is then inserted high into the rectum to prevent more fæces coming down, and the portion of bowel below this is well cleared with swabs. The swabs are removed after the injections are given.

Injections.—The technique of injecting piles must be learnt by practice. The two chief difficulties are deciding where to inject, and how to keep the mucous membrane under observation. The first ring of injections must be given above the piles; subsequent injections are given over the middle, or over the lower part of the piles, but never lower than a quarter of an inch above the white line. When using my speculum the position in relation to the white line can be ascertained by partly withdrawing the slide; with experience this becomes unnecessary. Often, when giving a posterior injection, a fold of mucous membrane is seen about one inch above the white line; injections cannot be given above this fold, and if given too close to it, the needle may pierce the whole fold. If, on withdrawing the obturator of the speculum, one attempts to inject, the mucous membrane is pushed away, the needle becomes hidden among the folds, and the actual site of injection cannot be watched. To avoid this, firmly rotate the speculum so as to isolate and fix the portion of mucous membrane where the injection is to be given. Thus, if the injection is to be into the left side, rotate the handle to the right. It is necessary to acquire this knack of rotating the speculum.

The guard is arranged to expose 0·5 cm. of the needle. All air is expelled from the syringe. The needle is pushed through the mucous membrane by a quick, sharp movement, and is changed after each injection. The injections are given as follows at weekly intervals: first, 2 c.cm. anterior; second, 2 c.cm. each, right and left; third, 2½ c.cm. each, anterior and posterior; fourth, 3 c.cm. each, right anterior and left posterior; fifth, 3 c.cm. each, left anterior and right posterior. These quantities are to serve as a guide only. The mucous membrane must be kept under observation while the injection is slowly given. At the first appearance of any whitening the injection is stopped, no matter how little has been given. Whitening is most often due to giving the injection into the mucous membrane instead of deep to it. Often the mucous membrane becomes distended over an area the size of a shilling, assumes a bluish appearance, and the bright red vessels can be distinctly seen. When this stippled appearance is produced the injection is stopped. The stippled appearance is to be aimed at, but must not be expected as a rule with the high injections or with those given towards the end of the treatment.

The subsequent course depends on the progress made. If there are now no symptoms the patient returns in two or three weeks, and a final injection is given. The rectum is examined, and the injections placed where they seem to be required. Most commonly this final treatment will be 2 c.cm. anterior, 2 c.cm. right posterior, and 2 c.cm. left posterior, as these are the most common sites for piles.

If the symptoms are still present after the fifth injection, the treatment is continued at weekly intervals. If the piles continue to prolapse, expose a little more of the needle, so as to inject more deeply into the pile. Limit the quantity given deeply at one point to a maximum of 3 c.cm. and do not inject with much force. If an injection will not go in with moderate force, then fibrosis is sufficient at that point. It is particularly necessary to make sure that the high injections have produced fibrosis. When the high injections have been proved to be efficient, then inject at a lower level. Occasionally it is necessary to give 10 or 12 injections to cure prolapse.

It is very rare for bleeding to persist after the fourth injection. If it persists after a few more low injections, then it is probably not coming from the piles and the case requires further investigation.

Complications.

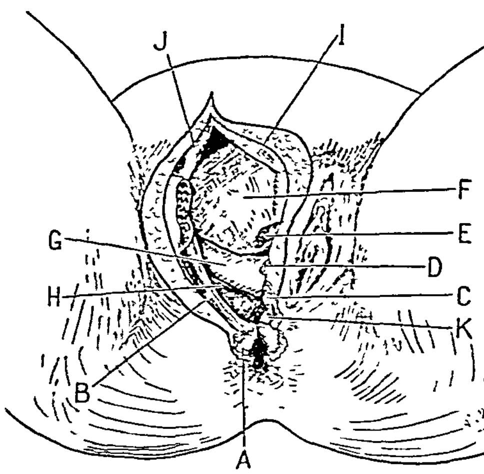
Various complications may occur in spite of the reports to the contrary. Most of these are probably due to the oil. The type of oil may not matter, but I am inclined to think that complications are more common after the use of almond oil.

1. *Unconsciousness.*—This occurred four times in about 300 cases, after the injection of 4–6 c.cm. All the cases were strong, healthy men, and unconsciousness occurred one or two hours after the first injection and lasted a few minutes. The patients felt well afterwards, and had no trouble with the subsequent injections. Mild symptoms, probably cerebral, that the patients find difficult to describe have occurred on rare occasions. Since limiting the first injection to a maximum of 2 c.cm. no cases of unconsciousness have occurred in the last two years.

2. *Influenza-like symptoms.*—These occur chiefly after the first injection, commence within 12 to 24 hours, and last one to three days. The temperature may reach 101° F. at night. In rare cases they may be repeated after the second injection, especially if it is given within a few days of the first. These symptoms have been practically eliminated since giving up the use of almond oil and menthol, not using a solution that has been made up for several weeks, and giving only 2 c.cm. at the first injection. More care has been taken with the sterilisation of all instruments, and water has not been allowed to come in contact with the solution.

there is sufficient force to split the urogenital triangle and wrench the pubic bones apart at the symphysis, which in the bent forward position is already under tension. Fig. III. shows the position of the seat relative to the perineum before an accident, the lines of force being directed through both ischial tuberosities. Fig. IV. shows the position of the seat caused by an accident, the line of force being directed through the urogenital triangle against the right pubic ramus.

FIG. V.



A, external sphincter; B, levator ani; C, bulbus vestibuli and bulbus cavernosus; D, crus clitoridis and ischiocavernosus; E, gracilis; F, bladder; G, vagina; H, rectum; I, medial head of rectus abdominis; J, lateral head of rectus abdominis; K, transversus perinæi.

The female pelvic outlet lends itself more than the male to the chance of this accident, because the female pubic arch is wider and more rounded. The pillars of the female arch "are somewhat excavated and sloped from within outwards, so that their inner surfaces look forward" (Gray), and present a larger area to any blow. The sharper the edge of the seat the more concentrated the force of injury.

A CASE.

This appears to have been the mechanical action in the following case where a motor bicycle, on trying to pass one car, was met by another coming in the opposite direction. The motor bicycle appeared to be thrown on its side, and skidded in that position for about 20 yards, taking the pillion rider with it. The driver died eight hours later from a very severe compound fracture of the right femur. The pillion rider, a girl aged 15 years, was admitted into Sutton Hospital at 10 P.M. on May 28th, 1931, in a state of severe collapse. Operation was performed two hours later. Inspection in the lithotomy position showed the injury as a large, well-defined tear beginning two inches above and one inch to the right of the symphysis pubis, and extending downwards through the right labium majus to and through the anterior wall of the anus. The right pubic bone fell away to the right of the middle line, showing a wound three inches in width, and exposing to view the bladder, vagina, and rectum. In detail the following anatomical damage was observed, and is shown in the accompanying sketch (Fig. V.).

Above the pubis.—The strong lateral head of the rectus abdominis was separated from the medial head of the rectus and from the pyramidalis for 2½ in. upwards, so exposing the cave of Retzius and the upper part of the bladder.

At the level of the symphysis pubis.—(1) The right pubic bone was separated from the fibro-cartilaginous symphysis. (2) Part of the right gracilis muscle, 1 in. in length, remained attached to the symphysis. (3) The subpubic ligament was torn across.

Through the urogenital triangle.—(1) The inferior layer of the urogenital fascia was torn in the line of the wound. (2) The crus clitoridis and the ischio-cavernosus muscle were torn from their attachments to the right ramus of the pubis and ischium. (3) Part of the right bulbo-cavernosus muscle was torn near its insertion into the perineal body. (4) The right transversus perinæi muscle was torn near its insertion into the perineal body. (5) The superior layer of the urogenital fascia was torn through and exposed the base of the bladder, the vaginal wall, the levator ani, and the lower part of the rectum. (6) The anterior border of the levator ani, running from the body of the pubis to the external sphincter and perineal body, was fully exposed, and the levator ani was completely separated from the vaginal wall.

Posterior to the urogenital triangle.—The anterior wall of the anus with the external sphincter muscle and fibres of the levator ani was completely torn across to a depth of 1½ in.

Operation.—1. The depth of the wound having been cleaned with spirit and saline, the pubic bone was drawn to the cartilage of the symphysis by silver wire passed in a mattress loop through both pubic bones. 2. The two heads of the rectus abdominis muscle were drawn together by interrupted catgut sutures. 3. The levator ani was united to the wall of the vagina by two fine catgut sutures. 4. The external sphincter and the torn levator ani fibres were united by deep and superficial catgut sutures. 5. For purposes of drainage, a piece of rubber glove was passed to the base of the bladder over the anterior edge of the levator ani. 6. The skin edges were drawn together by silkworm gut. 7. A rubber catheter was passed, and 3 oz. of slightly blood-stained urine were withdrawn. The catheter was retained for 48 hours, and liquid paraffin, ℥ss, was given thrice daily by mouth.

On the third day the catheter was withdrawn. Urine was passed voluntarily in the evening after an injection of pilocarpine gr. ¼. The vulvar parts were much swollen and discoloured, but there was no hæmaturia.

On the fourth day the rubber drain was removed and an enema was given. Urine was passed morning and evening after pilocarpine gr. ¼. On the seventh day full power was regained over micturition and defæcation.

For the first week there was a fair amount of purulent discharge from the wound which, with the exception of a small sinus at the upper end, healed completely at the end of four weeks. Two months after the injury the silver wire was removed by a transverse incision above the pubis, and firm fibrous union to the symphysis was demonstrated. A radiogram showed no other damage to the pelvis.

On the second day pitting œdema of the right leg and thigh was noticed. This cleared up in seven weeks, and obviously resulted from traumatic phlebitis of the right external iliac vein, probably due to sudden stretching. The only other associated injury was a lacerated flesh wound exposing tendons on the anterior surface of the right ankle-joint. It is probable that this was caused by a graze from the oncoming car.

The girl was able to walk out of hospital at the end of August.

Needless to say, the consequences of such an accident to a young woman may be very severe indeed, and although in these days of motor accidents pillion riders will always run the same risks as others, it may be that this particular form of accident can be prevented by the knowledge that sharply angulated saddles or seats are extremely dangerous.

SUGGESTIONS.

Pillion riding comes under the new "Road Traffic Act" of 1930 in so far that "only one pillion rider is to be carried and that person must sit astride on a proper seat securely fixed to the cycle." As far as I know, the Act makes no definition of what it means by "a proper seat." Three main types of pillion early cases where removal is easily possible it may still be preferred to radium, though radium has displaced surgery in all cases where extensive or mutilating operations would be necessary. In cases of removal of half the tongue, with well-planned incisions allowing of reconstruction, clear articulation is soon restored.

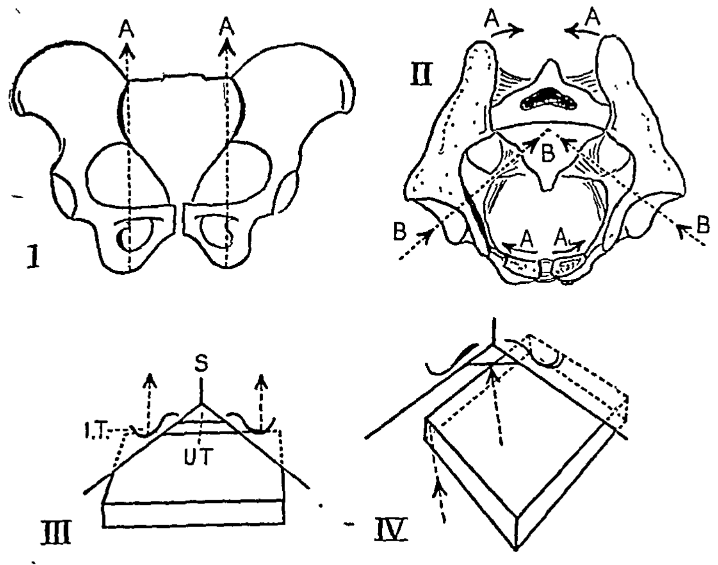
I have never before seen two separate primary malignant growths in the mouth. As there were three in this patient, I consider a record of the case may prove interesting.

THE PILLION RIDER'S PELVIC SPLIT ACCIDENT.

By J. M. Duff Mitchell, M.D., B.Sc. Aberd., F.R.C.S. Eng.,
HON. SURGEON, ST. ANTHONY'S HOSPITAL AND SUTTON AND CHEAM HOSPITAL.

A SUDDEN splitting of the soft tissues of the pubis *and perineum, accompanied by separation of the* pubic bones and exposure of pelvic viscera, without any fracture, is an accident which one would expect to occur fairly commonly in pillion riders. I am not aware, however, of a case having been hitherto recorded.

In studying the special mechanics of this accident in regard to stress and strain, the formation of the pelvis and its ligaments should be briefly considered. Normally a slight amount of movement can take place in the sacro-iliac joints, the sacrum rotating round an imaginary line drawn transversely through its second piece; this range of movement is increased in the pregnant woman. To quote Cunningham: "In the erect posture the promontory of the sacrum is withdrawn to the full extent from the symphysis. When the body is bent forwards the symphysis and the promontory are approximated and, in consequence, the tension of the sacro-tuberous and sacro-spinous ligaments is increased." The anterior sacro-iliac ligament, as compared with the strong posterior ligaments, is very weak indeed.



Figs. I.–IV. (explanation in text). In Fig. III.: S = symphysis; U.T. = urogenital triangle; I.T. = ischial tuberosity.

In the erect sitting posture the sacrum forms the keystone to an arch, the lines of stress passing from the ischial tuberosities through the outer angles of the keystone, thereby pressing the iliac articulating surfaces against the outward-spreading sacral articulations (arrow A in Fig. I.). In the bent forward position, however, the keystone effect of the sacrum does not exist. In this position the line of pressure is through the ilium behind or outside the sacro-iliac joint; at the same time there is a rotatory movement at the sacro-iliac joint, so tensing the posterior sacro-iliac ligaments. In other words, in the bent forward position the sacrum is, in a measure, suspended from the iliac bones by the posterior ligaments, so that the lines of tension pull the ilia together behind the sacro-iliac joints, and by a system of leverage —through these joints acting as fulcra—two opposing stretching forces are directed on the symphysis pubis (arrow A in Fig. II.). This stretching force at the pubic arch is taken advantage of by obstetricians when they recommend patients in the last stage of labour to adopt the bent forward lying down position.

In the quadruped or in the bent position in man, with the weight of the body passing through the extremities, this tendency to separation at the pubis is counteracted by lines of stress passing through the acetabula and directed in front of the sacro-iliac joints, using them as fulcra in an opposing system of leverage (arrow B in Fig. II.). Any strain directed outwards against the rami of the pubic arch in a rider bent forward with no counteracting pressure through the acetabula would, of course, add to this separating force at the symphysis. The same mechanism takes place in the operation of symphysiotomy, where there is a tendency for the pubic bones to separate too far, unless an assistant exerts pressure through the acetabula by pressing both hips together (Fig. II.).

The pillion rider generally sits with the body inclined forwards, and with the thighs flexed at an angle of 90° with the trunk. In the erect posture the pelvic brim forms an angle of 60° to the horizontal; in the bent forward position, therefore, the line of the pelvic brim is almost perpendicular to the plane of the saddle. Viewed from the front the thighs form an angle at the pubis of from 80° to 100°. The average maximum angle in this position is about 120°, that is, 15° to 20° more for either thigh if the opposite one is fixed to the saddle. Any sudden stretching of this angle by forcible abduction of either or both thighs may possibly have the following consequences: (1) throw the rider free from the bicycle on the other side; (2) capsize both rider and bicycle, the underlying leg being fixed or free; the relative position of seat to perineum may or may not be altered.

Injuries from extreme and sudden abduction may conceivably range in severity from rupture of the adductor muscles to dislocation of a hip-joint. It is extremely doubtful whether severe and sudden abduction produced by leverage at a point in the thigh below the perineum would be sufficient to cause separation of the pelvic bones. By the time the force reached the pelvis it would have spent itself in damage or dislocation to knee- or hip-joints. If, however, the position of the seat relative to the perineum is altered so that, combined with excessive abduction, there is a direct blow or force exercised by the edge of the rider's seat on one side of the urogenital triangle, and the patient was upset by the examination, which he described as bullying.

On the following day, while scribbling on a piece of paper—one of the methods employed for recall—he wrote down and recognised his surname, which was not "Arthur," although it began with A. Later he stated that his christian name was Arthur. On the next day he was pouring cream into his tea. "That's lovely rich cream," he said, "Mary would like that," and realised that he had spoken his wife's name.

For two days no more memories were obtained, and he became tense and panicky, saying he wanted to get out, and felt cooped up. This was met by putting his bed on an open verandah. It was noticeable, however, that the disturbance came at a time when his memory was well-nigh restored.

A week after his appearance in Perth his wife arrived. Recognition was immediate, and the patient became emotional and tearful. His wife's account of the events was that early on June 19th, while staying with her in their new home in Somerset, the patient said he was not at all well and had a headache. He went to see a physician who told him he was nervous, and to be careful. (Possibly this is the memory which he has misplaced back to Australia.) Leaving the physician he went to the bank, drew two hundred odd pounds, and disappeared. She confirmed the details of his life story as he had told it. She said he was a non-drinker, a moderate smoker, and a satisfactory husband. The £200 was the balance of the purchase price of a small business which they had decided to buy. They were going to settle down as small shopkeepers in a little village in Somerset, and he was, in fact, intending to complete the transaction that day.

When he left the hospital he had no more recollection, he said, of the events between leaving Australia and the day he appeared in Perth, than he had on admission to hospital.

The physician whom he saw on the day when his fugue took place, Dr. T. H. A. Pinniger, of Glastonbury, was struck by his manner. He was restless, said he had a headache, and feared insanity. There appeared to be no physical disorder, and he was clear mentally. He wished, however, to be given medical grounds for not going on with the business deal on which he was engaged. Dr. Pinniger again saw him after discharge, and noted that the only amnesic features were a failure to recognise the auctioneer who sold him the business, and the previous owner. By July 20th his memory was not much better, and he still failed to remember the voyage home and the business purchase. As well as this information his wife stated that his health had not been good for some time before leaving Australia. Details, however, are not given. We are much indebted to Dr. Pinniger for his help and notes on this case.

COMMENT.

We have no doubt that this was a genuine case of hysterical fugue with a very clear psychological motivation. The patient was a young, active, healthy, pyknic, "mixing" type. He had led a roving adventurous life. He was Australian born, thought there was no country like it, and had during examination refuted the suggestion that he might be going to settle in this country. Before he left he had been comfortably off in an attractive open-air billet. His wife, a quiet, cold type, did not like Australia and had induced him to sell out and come home to run a pastrycook's business in a country village. It became clear that he was appalled at the idea of "settling down" so very finally and completely as the situation before him implied. He had described in examination the tormenting recollection of adding up interminable figures, referring no doubt to the scrutiny of the accounts of the little shop.

Adequate conscious motive for his conduct was absent. He had paid beyond hope of recovery a considerable sum for the business, and the £200 was equally the sum required to complete the purchase and the last of his capital. Within not more than 15 hours of his disappearance in Somersetshire he deliberately put himself in the hands of the police in Perth and afforded such clues that, had they been widely and promptly circulated, were bound to have attracted his wife's attention at once. On the appearance of his wife he was obviously unfeignedly relieved and glad.

It is of importance that the memory loss was not of the "all or nothing" type. His memory was not restored intact in a flash. It was a fragmentary return, some of it fortuitous, some by painful effort, and the disturbance could clearly be better described as a dysmnesic rather than amnesic. The well-marked affective reaction was also of interest.

The taking of a railway ticket for Perth by this man who wanted to go back to Perth, W.A., goes far beyond mere plausibility, and is either inspiration—in which case he did not follow it up—or the genuine expression of a well-established hysterical phenomenon.

The scepticism of the police has already been mentioned. The possession of a large sum of money in unusual form by a rather shabby and unlikely individual, who could not account for himself or it, combined with their previous experience of apparently similar cases, and lastly the rapid production of valuable names and addresses during and after the police interrogation, contrasting with the slow and apparently reluctant recall of unhelpful details under medical methods, made the official opinion that the man was a malingerer very difficult to combat. (We ought to say that later the police were converted, and were most kind and helpful to the patient and his wife.) But the case demonstrates that the problems of the hysterical fugue, not matters of life and death as in war, yet present in civil life, present various medico-legal difficulties and call for the most careful investigation.

A CASE OF FOCAL OSTEITIS FIBROSA.

By G. B. Woodd Walker, M.B. Camb., F.R.C.S. Eng.,
ASSISTANT SURGEON TO THE WEST LONDON HOSPITAL.

(WITH ILLUSTRATIONS ON SPECIAL PLATE.)

THE case to be described is of special interest at the present time, when attention is being focused on osteitis fibrosa associated with parathyroid tumour and disturbance of calcium and phosphorus metabolism. No such metabolic disturbance could here be demonstrated and no general absorption of calcium was found; yet the wide distribution of the disease suggests that the condition is not completely described as "focal." L. Ollier (1899) noted its tendency to affect the homolateral extremities, while others [1-3] have remarked its association with the area of supply of a peripheral nerve; and these facts are probably significant.

The mode of onset, without pain or fracture, the degree of involvement of the skull, and the paraplegia from deformity of the spine make this case peculiar. It illustrates features of a disease with affinities, seats are on the market at the present time, and none of them eliminates the chance of this type of accident.

1. Probably the most used and the most dangerous is the oblong skeletal iron framework, fixed above the mudguard, on which can be strapped either luggage or a padded cushion for a pillion rider.
2. An iron oblong skeletal framework similar to the above, but having attached to it a number of spiral springs supporting a padded leather cushion. This is commonly used, and is capable of causing the above type of accident.
3. A pneumatic or sorbo leather cushion with no solid framework, attached to and resting on the mudguard, which in the modern motor bicycle is about 6 in. broad. This pattern, although much superior to the others, does not entirely eliminate danger from the edge of the mudguard or from the tool-bag cages, which are generally on either side of the mudguard.
4. As the best pattern I would suggest a design similar to a horse's saddle, fixed like (3) to the mudguard, but with padded side flaps, and given spring by means of enclosed air cushions.

I would also recommend that motor insurance companies should insist on having a design as free as possible from the dangers associated with the present types.

A CASE OF HYSTERICAL FUGUE.

By W. D. Chambers, M.D., F.R.C.P. Edin.,
MEDICAL SUPERINTENDENT, JAMES MURRAY'S ROYAL ASYLUM, PERTH;
AND
W. McC. Harrowes, M.D. Glasg., D.P.M.,
DEPUTY MEDICAL SUPERINTENDENT.

A case of hysterical fugue which recently passed through our hands is reported because, though according to the police-court reports in the daily press such cases are by no means rare, they do not often appear to be very closely investigated from the psycho-pathological point of view.

CASE-HISTORY.

About midnight on June 19th, 1931, a man of early middle age approached a constable in a street in Perth, N.B., and said to him: "Are you a policeman? Can you tell me where I am?" He was sober, clean and reasonably tidy, and his behaviour was conventional. He was told he was in Perth, and appeared surprised, saying: "This is not Perth—that's where I live." Assured that he was in Perth, Scotland, he said that he ought to be in Perth, Western Australia.

So normal did he otherwise seem to be that the constable, after a brief and unfruitful examination at the police office, guided him to an hotel where he was given a room in which he passed a sleepless night.

On the following day at noon he was seen by one of us. He looked physically well, but was worried, dejected, and uneasy. He wore a frown and was restless. He complained of a dull pressure type of frontal headache and of a sharp occipital pain. His conversation was clear, rational, and not retarded. Enunciation was clear. He stated that he could not recall his name, whence he came, or anything at all of his past history.

In his pocket had been found two Bank of England notes each of £100, a notebook containing business cards of a firm in Perth, W.A., and a number of addresses, and he had a few coppers. During interrogation he admitted a vague recollection of some business activities in Perth, W.A., and a few minutes later began to wonder if his name might be "Arthur" and his initials "A. A. A." It should be noted here that Arthur might have been a christian name or a surname. He seemed puzzled about the banknotes, and said that he had never seen them before, and would never carry notes of such a denomination or so much money. Also he could not understand why he had no cheque-book. He had a silver watch with the initials J. T. on it, knew they were not his initials, but was certain that the watch was his property. Search of the clothing was unhelpful. His hat, with the name of a Perth, W.A., hatter, had the initials "A. A. A." on the band, and was padded with a Perth, W.A., newspaper.

After consideration he was advised to go to hospital for observation and treatment, to which he willingly assented. He had more than once asked the doctor if he were "going insane," and if he would recover. On the way to the hospital he asked if he were being taken to an asylum.

On admission he was given treatment for his headache, and later divided doses of veronal totalling grs. xv. He was not questioned or disturbed, but reassured, and asked to refrain from forced efforts at recall.

Neurological and general physical examination revealed no abnormality. The mental status showed good retention and concentration. Calculation was well done. The orientation showed a fault (he said it was 1932), but was otherwise normal.

During the following 24 hours he slept almost continuously, waking for short intervals, and having a feeling of drowsiness and fatigue. Opportunity was taken of this to perform a hypnosis. The first attempt at hypnosis aimed at a light degree, and the suggestions were gradually made. He experienced some weariness and relaxation as suggested, but hypnotic closure of the eyes was not effected nor did he go into even a light hypnosis. In two hours, hypnosis was again attempted, using as suggestions the sensations experienced by him during the first attempt. Even with this generally powerful method no success resulted, indicating a high degree of resistance.

Recovery of memory was then begun on a conscious level by ordinary associational methods, and by initiating what might be expected to be stereotyped patterns of speech and thought. His thought content was investigated, and found to contain certain recurring items. These were the word Bristol, a memory of an automobile accident, the feeling that he had to catch a boat, the recollection of adding up columns of figures till he was wearied, and a vague idea that the £200 found in his pocket was for some business deal.

Gradually, in talk, he recovered an increasing number of details of his past, beginning from his early youth. He remembered his birthplace and birthday, school days and early jobs, his parents and his brothers and sisters. In this way he gave all his history in considerable detail up to and including the war years, at the end of which he had married. Thereafter he became more vague in chronology, but not in detail. This might have been normal, for he had been at many different places and had held a number of posts. The last clear memory was of being a real estate salesman in Perth, W.A., and of selling up his home as if to leave the country. He gave the street and number of the house he had there. He described a concussion with over a week's resultant unconsciousness, which had occurred when riding a steeplechase eight or nine years before.

Suddenly, while discussing some triviality at a break in the examination, he remembered the date of sailing from Australia and the name of the boat. He added that his wife had sailed before him, but could not remember if there were children with her. This recall seemed to bring some memories "to the tip of his tongue," where they were blocked against a marked resistance. Pictorial memories of the past were plentiful, but did not serve to fill in the amnesia. During examination with a sphygmomanometer he remembered having seen a physician before he left Australia, who warned him of a possible breakdown.

At this point the police intervened. The case had been reported in the local press. In the eyes of the police the patient was a simulator, either a criminal and a fugitive or a man who was attempting to extenuate or excuse a misdemeanour by a pretended loss of memory. They pointed out that within five years one of us had been consulted by them in three cases of alleged loss of memory, all of which had turned out to be simulation. Although two of these cases had not been subjected to a really searching test, in essence the police view was highly tenable.

He was seen by two detectives, who interrogated him for an hour and a half, telling him that in their eyes he was highly suspect. Under this pressure he recalled his wife's address, his father-in-law's name and address, and his sister-in-law's name. No other memories were obtained, cytes, 2 per cent.; lymphocytes, 32 per cent.); clotting time, normal: Wassermann and Kahn tests, negative.

Calcium Metabolism.—(Investigation by Dr. Donald Hunter.)

Date in 1931.	Serum calcium mg. per 100 c.cm	Plasma phosphorus mg. per 100 c.cm. (hæmolysed).	Plasma phosphatase.
Sept. 16th	9·6	2·8	0·650
„ 20th	9·5	2·3	0·640
„ 24th	10·0	2·0	0·327
„ 28th	9·7	2·8	—
Nov. 1st	9·6	3·8	—

On a *calcium-deficient diet* (306 g. per three-day period) the output of calcium was as follows:—Urine: period i., 0·28 g.; period ii., 0·30 g. (normal 0·17). Fæces: period i., 0·28 g.; period ii., 0·17 g. (normal 0·38). (Dr. Hunter.)

Urine.—Specific gravity, 1015. Acid. No Bence-Jones protein (six occasions).

Cerebro-spinal fluid.—(August 16th). Pressures: cistern, 130 mm. water; lumbar, 160 mm. water. After withdrawal of 1 c.cm. from cistern and lumbar regions: cistern, 130 mm. water; lumbar, 20 mm. water. Cerebro-spinal fluid from cistern: globulin not increased; total protein, 0·025. Cerebro-spinal fluid from lumbar: globulin much increased; total protein, 1·00. Cytology of both specimens undisturbed.

Slit-lamp report.—(Mr. C. E. Goulden): "In the centre of the fœtal nucleus of each lens there is a collection of fine opacities, which are not dense enough to interfere with vision. These belong to the earliest days of life."

Histology.—On Aug. 14th two fragments of rib were removed for examination and report. The tenth rib was normal bone, while the eleventh showed osteitis fibrosa. It was reported that there is no giant-celled tumour (myeloma) admixture.

Laminectomy was performed following a blood transfusion on Oct. 14th. The laminæ of the upper six, dorsal vertebræ were removed. Evidence of compression of the spinal cord at the level of the fourth vertebral body was found, pulsation below this level being absent, until the third lamina was removed. The spinal dura was not opened. No relief of symptoms has followed operation. X ray therapy has been given without obvious result.

I am much indebted to Dr. Donald Hunter, who admitted the patient to the London Hospital for investigation, and for the information thereby obtained. My thanks are due also to Dr. Redvers Ironside for the neurological investigation, and to Dr. H. M. Worth for the radiograms reproduced.

REVIEWS AND NOTICES OF BOOKS

Tumours of the Breast.

Their Pathology, Symptoms, Diagnosis, and Treatment. By Sir G. Lenthal Cheatle, K.C.B., C.V.O., F.R.C.S.; and Max Cutler, B.Sc., M.D. London: Edward Arnold and Co. 1931. Pp. 596. 50*s*.

For 35 years Sir Lenthal Cheatle has interested himself in the diseases of the mammary gland; this study has been his hobby as well as part of his profession, so that the subject must have occupied his thoughts during a large part of his life. His incidental publications have been numerous, and now, with the help of a younger American collaborator, Dr. Max Cutler, he has gathered together his accumulated material into one large volume. This forms so comprehensive a study of the diseases of the breast that wonder is immediately aroused as to why the title "Tumours of the Breast" should have been chosen. It is always pleasant to find more in a book than was expected instead of less, so that the surprise is of the right kind; and the volume must indeed contain the most detailed study of the diseases of the breast that has ever been published. Only the inflammatory lesions of the breast have been omitted, and these would in any case form but a small portion of a complete treatise.

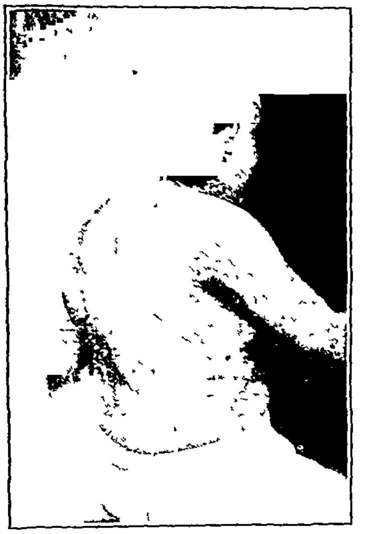
Sir Lenthal Cheatle has already published separate papers on "mazoplasia"—i.e., the "chronic mastitis" of other writers, on the genesis of carcinoma of the breast, and on Paget's disease of the nipple. All these subjects are here developed very fully, being preceded by exceedingly interesting chapters on the anatomy and physiology of the breast, congenital and acquired abnormalities, and "natural laws in pathological growth." There is nothing conventional about the views expressed and the outstanding value of his book lies in the fact that almost the whole of it is based on original observations. Original theory without an adequate basis of facts may always be mistrusted, but here this criticism is at once disarmed. The writings of other authors have been carefully sifted, and the listed references form a full index to the matter; but in addition the new theories are very fully documented with case-histories and illustrations of specimens and whole sections of the breast, cut by a special technique, which is described at the end of the book. The illustrations comprise, in fact, 18 coloured plates and 468 figures in the text, so that the authors' hope that the book may be used as an atlas as well as a work of reference is likely to be realised.

To the differentiation of mazoplasia from other innocent lesions of the breast prominent attention is given. It is claimed that this condition is really the result of a physiological process which is universally present up to the menopause, and few will nowadays question the propriety of abandoning the old name "chronic mastitis," with its unjustified implication of an inflammatory basis. There will be less general agreement as to making so clear-cut a distinction as is done by Sir Lenthal Cheatle between mazoplasia and the cystic lesions of the breast which may be lumped together under the name of "Schimmelbusch's disease." Some of the objections to his contentions have been urged by Mr. Sampson Handley in the Bradshaw lecture delivered last year before the College of Surgeons and published in these columns, and they may well be consulted. For this is probably the most arresting part of the book, since it has an important bearing on the genesis, and therefore the prophylaxis, of carcinoma of the breast. But extremely interesting to the specialist is Sir Lenthal Cheatle's very full account of Paget's disease of the nipple with descriptions of 17 specimens; this is, however, a rare condition, and is a relatively unimportant part of the general question of malignancy.

Sir Lenthal Cheatle's work is not intended to be a student's text-book, but is addressed rather to the pathologist and to the scientific surgeon. It is, in fact, one of those rare books, a clinical treatise inspired by a truly scientific spirit, so that every scrap of clinical evidence is used to the full, and every specimen obtained at operation or in the post-mortem room is scrutinised and made to yield its clinical and histological, to many other generalised and localised bone diseases, from Paget's disease to bone cysts—an affinity whose histological aspects have been well described by Lawford Knaggs.[4]

History.—The patient, a girl, 15 years of age, was perfectly fit until about three years ago, when she began to have difficulty in walking, and stiffness of the right knee, but without any pain. She was treated at the Tite-street Hospital for six months for flat-feet, and both ankles were in plaster for six months. After that the stiffness disappeared, and the patient was able to walk, though she was rather weak and unable to run. About nine months ago she became knock-kneed and was operated on at the Royal National Orthopædic Hospital. After this she was able to walk quite well, but still could not run. Later the difficulty in walking recurred, both legs being stiff, the right more than the left. In August, when admitted to West London Hospital, she could walk only very deliberately. She was quite well apart from the stiffness of legs and had never had any pain. She stated that she had had bony swellings over the left orbit and in the left little finger all her life. No fractures. No abdominal colic. Hearing good. Vision good. Action of bowels regular. Catamenia started at 13 years; regular, lasting three days. Micturition, no abnormality.

FIG. I.



Showing the irregular deformity of the head and the scolio-kyphosis of the spine. The operation scar for removal of portions of the tenth and eleventh ribs is seen on the right side.

Family history.—No history of bony abnormality or fractures. Mother, two brothers, one sister, one nephew (by sister) examined and found normal as regards skeleton. No history of bone defect in grandparents.

Physical examination. — Rather a slight girl, looks younger than her age. Weight, 6 st. 1 lb. Height, 4 ft. 5 in. Only slight development of breasts, but well-marked development of pubic hair. Teeth excellent. Tongue and throat clean. No enlarged glands, no œdema; no anæmia, jaundice, cyanosis, or clubbing. Sclerotics very slightly blue. No enlargement of the thyroid.

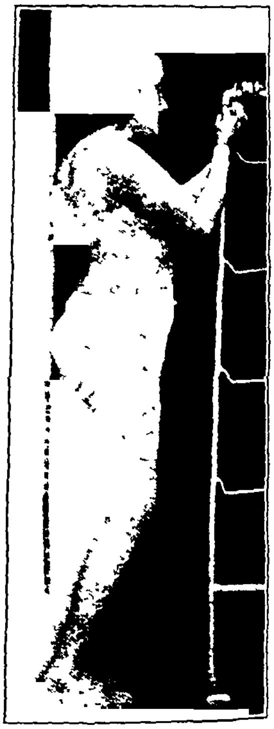
Cardiovascular system.—Apex-beat inside the mid-clavicular line; first and second sounds all areas. Blood pressure: 90 systolic, 50 diastolic.

Lungs.—Vesicular breathing, no added sounds.

Abdomen.—Slightly distorted from scoliosis (Figs I. and II.); nothing abnormal palpated; no tenderness.

Central nervous system.—Pupils equal, and central, react to light and accommodation. Cranial nerves normal. Upper limbs: deep reflexes present and equal, not exaggerated; no disturbance of motor or sensory functions. Trunk: abdominal reflexes absent: no band of hyperæsthesia detected, and no abnormalities of sensation; but on inspiration, muscles of the fourth intercostal space move well, muscles of the fifth space less well, and muscles of the sixth space not at all (Dr. George Riddoch). Lower limbs: marked spasticity in extension, especially of the right; very marked paresis; considerable wasting of calf muscles; knee-jerks exaggerated and equal; ankle-jerks exaggerated, right more than left; ankle-clonus present on the right side; plantar response, extensor, right and left; sensation to pinprick and touch appears normal; no loss of postural sense.

FIG. II.



Showing the good general nutrition of the patient. The spastic position of legs is well seen.

The main features of the skeleton are as follows:—

Skull.—(Fig. III.) Measures 22·5 in. in circumference, and is very irregular. There are three large bony bosses: (1) anteriorly, over the left frontal region, just outside the orbit, the size of a plum (4·5 by 2·5 by 1 cm. deep); (2) posteriorly, in the left occipito-parietal region, the size of an orange (15 by 10 by 5 cm.); (3) posteriorly, in the right occipital region, the size of a plum (6 by 5 by 1 cm.). These masses are not tender; they are merely prominences of the bone.

Limbs.—The limb bones are normal, except the ulnar half of the left hand (Fig. IV.), which shows a slight smooth bony swelling of the fourth and fifth metacarpals. The left little finger has a fixed flexion deformity. Rather excessive radial deviation of the forearms on the arms. Tibiæ 13·5 in. equal in length.

Spine.—(Figs. V. and VI.) There is marked scoliokyphosis, with the greatest curvature in the thoracic region to the right with winging of the right scapula. There is no tenderness of the spine, and no noticeable displacement of the vertebræ.

Ribs.—Slight irregularities can be felt. Harrison's sulcus is seen.

Pelvis.—Normal.

The following is a summary of the radiological reports.

Hands.—Union of all phalangeal and metacarpal epiphyses. Right, normal. Left (Fig. IV.), osteitis fibrosa of first, fourth, and fifth metacarpals; first, fourth, fifth prox. phalanges, and all phalanges of the third, fourth fingers. All epiphyses are joined almost five years before time.

Forearms and arms.—Nil, except epiphyseal advance.

Feet.—No loss of calcium, but possibly striæ in the patient are accentuated and possibly some loss of joint space. Epiphyseal advance.

Tibiæ.—Slightly less calcium than control. Definite linear rarefaction on zone of calcium decrease in region of epiphyseal line. Definite accentuation of striæ and bone pattern.

Femur.—Zone of decreased calcium deposit at epiphyseal line. Accentuation probably due to decrease in calcium deposit throughout. Deformity of lower end of femur, with buttressing on concave side. Upper epiphyses joined.

Pelvis.—The sacrum is prominent. Epiphysis at iliac crest not joined, other epiphyses joined two to three years before time.

Chest.—(Figs. V. and VI.). There is enormous deformity, most marked between the second and sixth vertebræ, with angulation at the fourth. Osteitis fibrosa affecting the vertebral bodies and the ribs on both sides.

Kidneys.—No evidence of renal calculus.

Special investigations gave the following results:—

Blood.—(August 25th) red cells, 5,030,000; hæmoglobin, 86 per cent.; leucocytes, 8400 (polymorph neutrophils, 55 per cent.; polymorph eosinophils, 1 per cent.; monocytes, 2 per cent.; lymphocytes, 32 per cent.); clotting time, normal; Wassermann and Kahn tests, negative.

Calcium Metabolism.—(Investigation by Dr. Donald Hunter.)

Date in 1931.	Serum calcium mg. per 100 c.cm.	Plasma phosphorus mg. per 100 c.cm. (hæmolysed).	Plasma phosphatase.
Sept. 16th	9·6	2·8	0·650
„ 20th	9·5	2·3	0·640
„ 24th	10·0	2·0	0·327
„ 28th	9·7	2·8	—
Nov. 1st	9·6	3·8	—

On a *calcium-deficient diet* (306 g. per three-day period) the output of calcium was as follows:—Urine: period i., 0·28 g.; period ii., 0·30 g. (normal 0·17). Fæces: period i., 0·28 g.; period ii., 0·17 g. (normal 0·38). (Dr. Hunter.)

Urine.—Specific gravity, 1015. Acid. No Bence-Jones protein (six occasions).

Cerebro-spinal fluid.—(August 16th). Pressures: cistern, 130 mm. water; lumbar, 160 mm. water. After withdrawal of 1 c.cm. from cistern and lumbar regions: cistern, 130 mm. water; lumbar, 20 mm. water. Cerebro-spinal fluid from cistern: globulin not increased; total protein, 0·025. Cerebro-spinal fluid from lumbar: globulin much increased; total protein, 1·00. Cytology of both specimens undisturbed.

Slit-lamp report.—(Mr. C. E. Goulden): "In the centre of the fœtal nucleus of each lens there is a collection of fine opacities, which are not dense enough to interfere with vision. These belong to the earliest days of life."

Histology.—On Aug. 14th two fragments of rib were removed for examination and report. The tenth rib was normal bone, while the eleventh showed osteitis fibrosa. It was reported that there is no giant-celled tumour (myeloma) admixture.

Laminectomy was performed following a blood transfusion on Oct. 14th. The laminæ of the upper six dorsal vertebræ were removed. Evidence of compression of the spinal cord at the level of the fourth vertebral body was found, pulsation below this level being absent, until the third lamina was removed. The spinal dura was not opened. No relief of symptoms has followed operation. X ray therapy has been given without obvious result.

I am much indebted to Dr. Donald Hunter, who admitted the patient to the London Hospital for investigation, and for the information thereby obtained. My thanks are due also to Dr. Redvers Ironside for the neurological investigation, and to Dr. H. M. Worth for the radiograms reproduced.

REVIEWS AND NOTICES OF BOOKS

Tumours of the Breast.

Their Pathology, Symptoms, Diagnosis, and Treatment. By Sir G. LENTHAL CHEATLE, K.C.B., C.V.O., F.R.C.S.; and MAX CUTLER, B.Sc., M.D. London: Edward Arnold and Co. 1931. Pp. 596. *50s.*

FOR 35 years Sir Lenthal Cheatle has interested himself in the diseases of the mammary gland; this study has been his hobby as well as part of his profession, so that the subject must have occupied his thoughts during a large part of his life. His incidental publications have been numerous, and now, with the help of a younger American collaborator, Dr. Max Cutler, he has gathered together his accumulated material into one large volume. This forms so comprehensive a study of the diseases of the breast that wonder is immediately aroused as to why the title "Tumours of the Breast" should have been chosen. It is always pleasant to find more in a book than was expected instead of less, so that the surprise is of the right kind; and the volume must indeed contain the most detailed study of the diseases of the breast that has ever been published. Only the inflammatory lesions of the breast have been omitted, and these would in any case form but a small portion of a complete treatise.

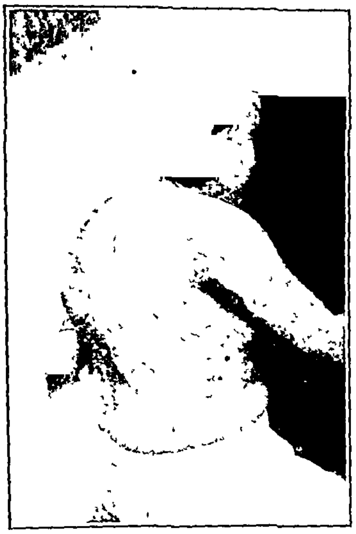
Sir Lenthal Cheatle has already published separate papers on "mazoplasia"—i.e., the "chronic mastitis" of other writers, on the genesis of carcinoma of the breast, and on Paget's disease of the nipple. All these subjects are here developed very fully, being preceded by exceedingly interesting chapters on the anatomy and physiology of the breast, congenital and acquired abnormalities, and "natural laws in pathological growth." There is nothing conventional about the views expressed and the outstanding value of his book lies in the fact that almost the whole of it is based on original observations. Original theory without an adequate basis of facts may always be mistrusted, but here this criticism is at once disarmed. The writings of other authors have been carefully sifted, and the listed references form a full index to the matter; but in addition the new theories are very fully documented with case-histories and illustrations of specimens and whole sections of the breast, cut by a special technique, which is described at the end of the book. The illustrations comprise, in fact, 18 coloured plates and 468 figures in the text, so that the authors' hope that the book may be used as an atlas as well as a work of reference is likely to be realised.

To the differentiation of mazoplasia from other innocent lesions of the breast prominent attention is given. It is claimed that this condition is really the result of a physiological process which is universally present up to the menopause, and few will nowadays question the propriety of abandoning the old name "chronic mastitis," with its unjustified implication of an inflammatory basis. There will be less general agreement as to making so clear-cut a distinction as is done by Sir Lenthal Cheatle between mazoplasia and the cystic lesions of the breast which may be lumped together under the name of "Schimmelbusch's disease." Some of the objections to his contentions have been urged by Mr. Sampson Handley in the Bradshaw lecture delivered last year before the College of Surgeons and published in these columns, and they may well be consulted. For this is probably the most arresting part of the book, since it has an important bearing on the genesis, and therefore the prophylaxis, of carcinoma of the breast. But extremely interesting to the specialist is Sir Lenthal Cheatle's very full account of Paget's disease of the nipple with descriptions of 17 specimens; this is, however, a rare condition, and is a relatively unimportant part of the general question of malignancy.

Sir Lenthal Cheatle's work is not intended to be a student's text-book, but is addressed rather to the pathologist and to the scientific surgeon. It is, in fact, one of those rare books, a clinical treatise inspired by a truly scientific spirit, so that every scrap of clinical evidence is used to the full, and every specimen obtained at operation or in the post-mortem room is scrutinised and made to yield its clinical and histological, to many other generalised and localised bone diseases, from Paget's disease to bone cysts—an affinity whose histological aspects have been well described by Lawford Knaggs.[4]

History.—The patient, a girl, 15 years of age, was perfectly fit until about three years ago, when she began to have difficulty in walking, and stiffness of the right knee, but without any pain. She was treated at the Tite-street Hospital for six months *for flat-feet, and both ankles were in plaster for* six months. After that the stiffness disappeared, and the patient was able to walk, though she was rather weak and unable to run. About nine months ago she became knock-kneed and was operated on at the Royal National Orthopædic Hospital. After this she was able to walk quite well, but still could not run. Later the difficulty in walking recurred, both legs being stiff, the right more than the left. In August, when admitted to West London Hospital, she could walk only very deliberately. She was quite well apart from the stiffness of legs and had never had any pain. She stated that she had had bony swellings over the left orbit and in the left little finger all her life. No fractures. No abdominal colic. Hearing good. Vision good. Action of bowels regular. Catamenia started at 13 years; regular, lasting three days. Micturition, no abnormality.

FIG. I.



Showing the irregular deformity of the head and the scolio-kyphosis of the spine. The operation scar for removal of portions of the tenth and eleventh ribs is seen on the right side.

Family history.—No history of bony abnormality or fractures. Mother, two brothers, one sister, one nephew (by sister) examined and *found normal as* regards skeleton. No history of bone defect in grandparents.

Physical examination. — Rather a slight girl, looks younger than her age. Weight, 6 st. 1 lb. Height, 4 ft. 5 in. Only slight development of breasts, but well-marked development of pubic hair. Teeth excellent. Tongue and throat clean. No enlarged glands, no œdema; no anæmia, jaundice, cyanosis, or clubbing. Sclerotics very slightly blue. No enlargement of the thyroid.

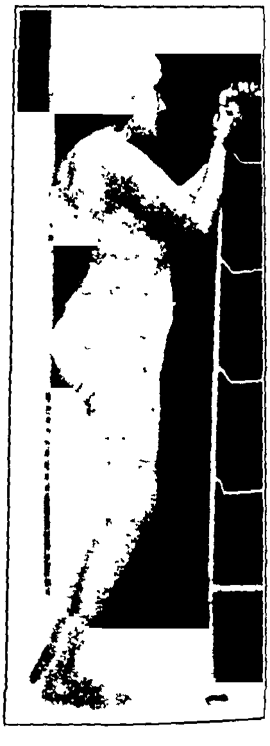
Cardiovascular system.—Apex-beat inside the mid-clavicular line; first and second sounds all areas. Blood pressure: 90 systolic, 50 diastolic.

Lungs.—Vesicular breathing, no added sounds.

Abdomen.—Slightly distorted from scoliosis (Figs I. and II.); nothing abnormal palpated; no tenderness.

Central nervous system.—Pupils equal, and central, react to light and accommodation. Cranial nerves normal. Upper limbs: deep reflexes present and equal, not exaggerated; no disturbance of motor or sensory functions. Trunk: abdominal reflexes absent: no band of hyperæsthesia detected, and no abnormalities of sensation; but on inspiration, muscles of the fourth intercostal space move well, muscles of the fifth space less well, and muscles of the sixth space not at all (Dr. George Riddoch). Lower limbs: marked spasticity in extension, especially of the right; very marked paresis; considerable wasting of calf muscles; knee-jerks exaggerated and equal; ankle-jerks exaggerated, right more than left; ankle-clonus present on the right side; plantar response, extensor, right and left; sensation to pinprick and touch appears normal; no loss of postural sense.

FIG. II.



Showing the good general nutrition of the patient. The spastic position of legs is well seen.

The main features of the skeleton are as follows:—

Skull.—(Fig. III.) Measures 22·5 in. in circumference, and is very irregular. There are three large bony bosses: (1) anteriorly, over the left frontal region, just outside the orbit, the size of a plum (4·5 by 2·5 by 1 cm. deep); (2) posteriorly, in the left occipito-parietal region, the size of an orange (15 by 10 by 5 cm.); (3) posteriorly, in the right occipital region, the size of a plum (6 by 5 by 1 cm.). *These masses are not tender;* they are merely prominences of the bone.

Limbs.—The limb bones are normal, except the ulnar half of the left hand (Fig. IV.), which shows a slight smooth bony swelling of the fourth and fifth metacarpals. The left little finger has a fixed flexion deformity. Rather excessive radial deviation of the forearms on the arms. Tibiæ 13·5 in. equal in length.

Spine.—(Figs. V. and VI.) There is marked scolio-kyphosis, with the greatest curvature in the thoracic region to the right with winging of the right scapula. There is no tenderness of the spine, and no noticeable displacement of the vertebræ.

Ribs.—Slight irregularities can be felt. Harrison's sulcus is seen.

Pelvis.—Normal.

The following is a summary of the radiological reports.

Hands.—Union of all phalangeal and metacarpal epiphyses. Right, normal. Left (Fig. IV.), osteitis fibrosa of first, fourth, and fifth metacarpals; first, fourth, fifth prox. phalanges, and all phalanges of the third, fourth fingers. All epiphyses are joined almost five years before time.

Forearms and arms.—Nil, except epiphyseal advance.

Feet.—No loss of calcium, but possibly striæ in the patient are accentuated and possibly some loss of joint space. Epiphyseal advance.

Tibiæ.—Slightly less calcium than control. Definite linear rarefaction on zone of calcium decrease in region of epiphyseal line. Definite accentuation of striæ and bone pattern.

Femur.—Zone of decreased calcium deposit at epiphyseal line. Accentuation probably due to decrease in calcium deposit throughout. Deformity of lower end of femur, with buttressing on concave side. Upper epiphyses joined.

Pelvis.—The sacrum is prominent. Epiphysis at iliac crest not joined, other epiphyses joined two to three years before time.

Chest.—(Figs. V. and VI.). There is enormous deformity, most marked between the second and sixth vertebræ, with angulation at the fourth. Osteitis fibrosa affecting the vertebral bodies and the ribs on both sides.

Kidneys.—No evidence of renal calculus.

Special investigations gave the following results:—

Blood.—(August 25th) red cells, 5,050,000; hæmoglobin, 86 per cent.; leucocytes, 8100 (polymorph neutrophils, 55 per cent.; polymorph eosinophils, 1 per cent.; mono-use. The book has been prepared under the auspices of the American Association of Clinical Pathologists, and all methods included have had the sanction of at least five members of the Association. That some standardisation of clinical pathological methods is desirable there can be no doubt. The work has been undertaken under the wise direction of Prof. Kolmer; it should find a place in every up-to-date pathological laboratory.

The first edition of Prof. Todd's work appeared in 1908; since then, as Prof. Todd remarks in his introduction, "clinical pathology has undergone marvellous development and the book has of necessity grown in size and scope with each new edition." It has long been known throughout the English-speaking world and there must be few pathological laboratories either in this country or America in which it is not frequently consulted. This seventh edition, like all its predecessors, shows discrimination in the choice of simple and yet efficient methods of technique and in disregard of the unessential. These characteristics make it peculiarly valuable to the student.

"Bedside Interpretation of Laboratory Findings" is a book by a clinician and for clinicians. Prof. Wohl shows a proper sense of the place played by laboratory procedures in modern medicine, and his interpretation of their results is sound and well balanced. While urging the practitioner to perform his own examinations where possible, he recognises that there are many procedures which are quite beyond either the time at the disposal of the clinician or the capacities of his "office" apparatus. It is doubtful if anyone even with the help of such a book as this can correctly interpret the results of a laboratory test unless he himself be fully conversant with its technique; the converse proposition—that no test, not even the Wassermann reaction, can be correctly interpreted in the absence of full knowledge of the individual case is given full weight by Prof. Wohl. In face of the present widespread belief that it is possible satisfactorily to divorce the laboratory worker and the clinician this truth cannot be restated too often. Prof. J. McFarland, of the Department of Pathology of the University of Pennsylvania, contributes an introduction in which he deplores the disappearance of the "old time family doctor," a class which, according to him, must now be relegated to the "company of medicine men, magicians, and priests of antiquity." This seems a somewhat hard judgment. Fortunately in this country the family doctor is still with us and it is in particular to him that Prof. Wohl's book will be of value.

Headache.

By William H. Robey, M.D., Clinical Professor of Medicine, Harvard Medical School. London: J. B. Lippincott Company. 1931. Pp. 234. 21s.

Prof. Robey, like most writers on headache, comments on the frequency with which the symptom is encountered and the multiplicity of causes that may be responsible for it, as well as on the difficulty of classification and complete comprehension. On the whole, he has been as successful as any of his predecessors, and his monograph may be recommended as a reliable guide. It is regrettable that in places the style is careless and even slovenly, although three colleagues are indicated as associated with proof reading. The arrangement employed in the formation of paragraphs with arresting headlines is occasionally peculiar.

The material too is uneven: there is disproportionate detail in some chapters; in others the subject receives scant presentation. The allotment of only two and a half pages to drug treatment is certainly inadequate. Admittedly the first consideration of a physician when confronted with a case of headache is to isolate the cause in the hope of employing appropriate measures, but it falls to the lot of every practitioner to be frequently compelled to resort to purely symptomatic treatment; and something more than mere enumeration or formal reference to the properties of the numerous analgesics in use is expected in a monograph. The author sometimes allows himself to be diverted from his subject. Having mentioned that trichiniasis may cause headache, he proceeds to an unnecessarily detailed clinical study of a case in his experience: a reference to mercury leads to the description of a sensational suicide by corrosive sublimate. Alcohol is admittedly a cause of headache, but that hardly justifies a somewhat undignified reference to dipsomaniacs and secret drinking. And whilst the information imparted in the analysis of the causes and treatment of constipation is unexceptionable, it is out of place in the present connexion. The chapter on migraine stands out as authoritative, though we do not share the author's regret that patients are not properly instructed by their physicians in the examination of their excreta. The statistics in connexion with cerebral tumours are most instructive and useful. The defects of Prof. Robey's book are especially noticeable because parts of his book are so good.

Elektrophorese, Elektro-osmose, Elektrodialyse in Flüssigkeiten.

By P. H. Prausnitz, Dr.-Ing. (Jena), and J. Reitstötter, Dipl-Ing., Dr. Phil., Dr. Techn. (Berlin). Dresden and Leipzig: Theodor Steinkopff. 1931. Pp. 307.

This treatise, which the authors rightly describe as a compilation of facts in which as far as is possible unproved hypotheses have been avoided, deals with the phenomena which appear when electric fields are applied to colloidal systems in the broadest sense. The three factors concerned in electrophoresis, electro-osmose, and streaming potentials are a potential difference between the liquid and particles therein, relative motion between them, and a potential between two electrodes in the liquid. If a potential be so applied, motion occurs, the particles moving if they be suspended in the liquid, or the liquid moving if the particles be fixed as a diaphragm; conversely, if relative motion be applied by forcing the liquid through a diaphragm a P.D. is set up between the electrodes. These phenomena depend in magnitude on the electrokinetic potential, and the exact part of the book is concerned largely with the modification of the electrokinetic potentials by many important factors, such as dielectric constant, adsorption, nature of the particles, and of the ions in the solution. Electrodialysis, the promotion and acceleration of true dialysis by application of an electric potential difference, is linked to the other phenomena discussed by its dependence on the permeability of membranes. The authors are to be congratulated on using the term "elektrophorese" exclusively; since the great proportion of particles in watery media migrate to the anode, the popularity of the term "kataphoresis" is to be wondered at. "Elektro-osmose" is used instead of the longer "elektro-endosmose."

Apart from the treatment of the purely scientific aspect of these phenomena and a fully illustrated share of ocular demonstration. The authors have carried out their task admirably and have received from their publishers excellent technical support.

Science and Practice of Dental Surgery.

Second edition. Edited by Sir Norman Bennett, M.A., M.B., L.D.S., Consulting Dental Surgeon to St. George's Hospital and the Royal Dental Hospital. London: Oxford University Press, Humphrey Milford. 1931. Two vols. Pp. 1568. £4 4*s.*

The first edition of this book was published as long ago as 1914, and it is common knowledge that the appearance of this edition has been eagerly awaited for some years. But the task of revising thoroughly a book on such a large scale as this, especially in view of the many advances which have been made in dentistry, must have been very great. The first edition was in one volume with double columns of type. In many respects it was unwieldy and awkward to handle, while the illustrations were not always adequate. This edition has been expanded into two volumes and at the same time considerably enlarged. The paper is better and the illustrations, which are of excellent quality, have been increased from 993 to over 1200.

The revision has been thorough and in many cases the articles are entirely fresh. It is significant of the growth of orthodontics that the greater part of the first volume, over 600 pages, is devoted to this subject from the pens of the Editor and Mr. H. Chapman. Some may regard such an allocation as excessive in a book which is intended for the general practitioner, and in view of the comparatively small part which orthodontics play in dental practice. But while the general usefulness of this book might have been increased if some of the space devoted to orthodontics had been allotted to other subjects which are treated with considerable brevity—such as local anæsthesia which is not adequately described—yet the school of dental surgeons, which is interested particularly in orthodontics, will be grateful for the masterly exposition supplied by the editor. It is inevitable that in a book with many contributors the sections should be of unequal value and that overlapping and lacunæ will both exist, but the most serious risk, that of contradictory statements, is avoided. Readers according to their special predilections may cavil at the excessive space given to some subjects and the scanty measure granted to others. But on whatever aspect of dentistry information is sought, with only the rarest exceptions, a sound account will be found.

We note with some regret that the section on the legal aspects of dentistry which appeared in the first edition has been omitted, for this is a subject of great importance, and the practitioner might have been greatly aided had an authoritative section on the legal complications of dental practice been included. Among the various sections a few may be singled out for special praise. The chapter on gold inlays, by J. G. Parfitt, is a masterly account, clear and concise. The chapter on odontomes, by W. James and E. A. Councell, is full of interest, and contains some new matter bearing on the ætiology of dental cysts and granulomata of a quite startling character. The chapter on fractures of the jaws, by Kelsey Fry, is another excellent résumé. The practitioner who desires to keep abreast of advances in dental surgery will add these volumes to his library.

Laboratory Diagnosis.

By Edwin E. Osgood, M.A., M.D., Assistant Professor of Medicine and Biochemistry, University of Oregon School of Medicine; and Howard D. Haskins, M.D., Professor of Biochemstry at the School. London: J. and A. Churchill. 1931. Pp. 475. 21*s.*

Approved Laboratory Technique.

Prepared under the Auspices of the American Association of Clinical Pathologists. By John A. Kolmer, M.D., Dr. P.H., Professor of Pathology and Bacteriology, Graduate School of Medicine, University of Pennsylvania; and Fred Boerner, V.M.D., Associate Professor of Bacteriology at the School. Assisted by C. Zent Garber, A.B., M.D., Associate in Pathology, Peking Union Medical College. London: D. Appleton and Co. 1931. Pp. 663. 30*s.*

Clinical Diagnosis by Laboratory Methods.

Seventh edition. By J. Campbell Todd, Ph.B., M.D., late Professor of Clinical Pathology, University of Colorado; and Arthur H. Sanford, Professor of Clinical Pathology, University of Minnesota. London: W. B. Saunders Co., Ltd. 1931. Pp. 765. 28*s.*

Bedside Interpretation of Laboratory Findings.

By Michael G. Wohl, M.D., Associate Professor of Experimental Medicine, Temple University Medical School. London: Henry Kimpton. 1931. Pp. 321. 25*s.*

Prof. Osgood and his collaborator have adopted the somewhat unusual plan of dividing their work into two parts, the first dealing with indications and interpretations, and the second with technique. This gives the volume an interesting outlook wider than that of the ordinary text-book on clinical pathology. The first part will be of interest to those not actually engaged in the performance of laboratory aids to diagnosis. It is comprehensive and, on the whole, sound. The authors have shown originality in including a section on the clinical pathology of pregnancy, a subject which is usually passed over in works of this sort; this is not the strongest section of the book, but is of definite value. To speak of eclampsia as a "specific" toxæmia of pregnancy bespeaks optimism as to the state of our knowledge of the ætiology and pathology of this syndrome; and the assurance that eclampsia does not tend to occur in successive pregnancies must not be accepted without reservations. The effect of liver in the so-called "pernicious anæmia of pregnancy" awaits conclusive proof; the authors fail to mention the sovereign virtue of blood transfusion in this condition. Improvements resulting in simplification of the technique have made the Zondek-Aschheim reaction a less formidable undertaking than the description implies. Taken as a whole, however, the first part of the book should be of real value to students and practitioners, clinicians and laboratory workers alike. The section on technique is all that it should be; as might be expected from authors whose work on the normal blood has brought them an international reputation, Prof. Osgood and Prof. Haskins have provided a section on blood examinations which is particularly valuable.

The authors of "Approved Laboratory Technique" express the hope that it will promote the establishment of standards for the performance of the diagnostic laboratory procedures in general

Reminders and Suggestions

For the Treatment of INFLUENZA, PNEUMONIA, COUGHS, COLDS, BRONCHITIS, etc.

KINECTINE

An organic arsenical salt of Quinine indicated in Influenza, Acute Coryza, etc.

Tubes of 10 Tablets: Dose—One three times a day.

CRYOGENINE (Lumière)

A particularly safe and reliable analgesic and antipyretic in all febrile conditions. Bronchitis, Pneumonia, Influenza, Pleurisy

Powder and Tablets: Dose—From 0·50 to 2·50 gm. daily as required.

ORARGOL

An electrically prepared Gold-Silver Colloid for general antisepsis and effective colloidotherapy.

Ampoules of 5 c.c. and 10 c.c.

By intravenous or intramuscular injection Orargol is capable of aborting serious cases of Influenza and Pneumonia, and exerts an antitoxin-like effect in acute infectious conditions.

Also supplied in special O.R.L. Outfit for Nasal Irrigation in the treatment of Rhinitis, Tonsillitis and Naso-pharyngeal inflammations.

Extremely valuable as a prophylactic against Colds and Influenza.

SYRUP CREOSAL (Dubois)

A combination of Guaiacol, Calcium and Phosphoric Acid pleasantly flavoured with Syrup of Orange Flower & Cherry Laurel.

An excellent specific for Coughs—whatever their origin—Bronchitis, Laryngitis, and all Catarrhal Conditions.

SYRUP PERTUSSIS (Gabail)

A combination of deodorised Valerianate, expectorants and sedatives presented in a palatable form with Syr. of Raspberry.

An effective medicament for the Paroxysms of Whooping Cough.

LITERATURE AND SAMPLES ON REQUEST FROM

The Anglo-French Drug Co., Ltd.,
238a, Gray's Inn Road, LONDON, W.C.1.

description of various ingenious types of apparatus, a large portion of the book is devoted to practical and industrial applications. The patent literature is abstracted at great length. In addition to the large number of references in the text, an extensive bibliography and a patent index complete a really modern reference book of great value. The application of the principles of electrophoresis and endosmose may well prove to be of great value in biology. Little has so far been done, but it seems that they may provide a weapon for the differentiation of proteins. Again, the electric charges on bacteria may be studied. For the purification of sera and antitoxins electrodialysis has been used; this is a field in which Dr. Reitstötter has done much work. But from the direct application of in-vitro results to processes in the living organism we are especially warned by the authors.

L'Anesthésie.

En pratique chirurgicale. By R. MONOD, Chir. des Hôpitaux de Paris. Paris: Masson et Cie. 1931. Pp. 154. Fr.22.

THIS small book gives a clear exposition of the principles on which general and local anæsthetics are best employed. Details of administration of various anæsthetics, and of the phenomena produced by their introduction into the body, are not, as a rule, attempted, but the reader is given sound and logical guidance in the choice of an anæsthetic, and the appropriate method of giving it to various kinds of patients and in different circumstances. The author has no predilection for any one method, pointing out forcibly that to-day there are many good methods and several anæsthetics, and that although a routine method may be satisfactory in many instances, yet there are many others where the surgeon's facility and the patient's good recovery can only be assured by selecting the method best suited to the particular condition present in the individual case. A surprising feature is the space and number of illustrations given to the subject of choloroform administration by apparatus of the "draw-over" type—a technique which we regard as almost obsolete. The administration of ethylchloride continuously for long operations is described, but adequate "gas and oxygen" apparatus for the same purpose is very inadequately noticed. Endotracheal anæsthesia has apparently not yet crossed the Channel, and the pages on spinal analgesia are meagre considering the importance of the method. On the other hand, the chapter on examining and treating patients before serious operations is excellent, and contains information not often found in books of this kind.

The Cause of Cancer.

By W. E. GYE and W. J. PURDY, M.B., Members of the Scientific Staff of the National Institute for Medical Research. London: Cassell and Co., Ltd. 1931. Pp. 515. 30s.

THIS important work contains controversial matter which cannot adequately be discussed in our review columns. A special article by Dr. W. Cramer on the latest developments of Dr. Gye's work, as set out in this book, will be found on p. 40 of this issue.

British Journal of Children's Diseases.

THE latest number of this journal (Vol. XXVIII., October–December, 1931) contains a paper on Experimental Scarlet Fever by Means of the Scarlatinal Hæmolytic Streptococcus, by Drs. T. Toyoda, Y. Futagi, and M. Okamoto, of the Japanese Government Isolation Hospital, Dairen, Manchuria. They record the inoculation of e[illegible] 3 to 7 years, by swabbing thei[illegible] of hæmolytic streptococci from scarlet fever cases. Positive results were obtained in three cases in which new strains of streptococci were applied, as shown by the appearance of sore-throat, fever, a rash, and a positive Schultz-Charlton reaction, whereas similar experiments undertaken on five cases with old strains of scarlatinal streptococci proved negative.—Dr. F. G. Wood-Smith, who contributes a paper on Purpura in Scarlet Fever, states that this is a rare complication. Both sexes are equally affected, but children more commonly than adults. The purpura, which is probably due to capillary damage caused by the toxin of the scarlatinal streptococcus, may develop during the course of any type of scarlet fever, whether mild or severe, the commonest time for its appearance being the third week of the disease. The platelet count, though often decreased, may be normal. All forms of purpura in varying degrees of severity may be encountered.—In a paper on Hair-eating and Pica in Children, Dr. Jean Smith reports the case of a girl, aged 3 years, who during six weeks passed four hair balls per rectum. On inquiry it was found that she had been in the habit not only of swallowing the hairs from blankets, but also eating wall-plaster and pieces of wood. Dr. Smith regards pica as a bad habit similar to thumb sucking, nail biting, masturbation, and some cases of enuresis, in which bad feeding, lack of training, poor surroundings, and limitation of interests all play a part.—Dr. W. Gordon Sears describes a case of Dwarfism with Stippled Epiphyses in a youth aged 19, the most striking features being the radiogram of transverse striation of the epiphyses of the femora and tibiæ.—In a paper on Helminths as a Cause of Meningitis, Dr. L. J. M. Laurent reports a case in a girl aged 3½ years sent to hospital certified as suffering from cerebro-spinal meningitis, the symptoms being vomiting, convulsions, photophobia, nuchal rigidity, and general irritability followed by drowsiness. The cerebro-spinal fluid, though under pressure, was clear and sterile, and recovery took place after evacuation of a large quantity of thread-worms. Reference is made to other cases of meningism or meningitis due to worms.—In addition to society intelligence, the issue contains an account of the International Congress of Preventive Pædiatrics held at The Hague last September, when the subjects for discussion were the mortality during the first ten days of life and return cases of scarlet fever. The index appended forms a useful guide to contemporary pædiatric literature.

REPORTS AND ANALYSES

TINTARA.

(P. B. BURGOYNE AND CO., BURGOYNE HOUSE, DOWGATE HILL, E.C.)

THIS Australian wine has been well known to the medical profession for very many years and has again been analysed with the following results.

Alcohol by volume	15·3 per cent.
Total extractives	2·31 " "
Containing sugar	0·50 " "
Fixed acidity (as tartaric acid) ..	0·49 " "
Volatile acidity (as acetic acid) ..	0·05 " "
Mineral matter	0·42 " "
Tannin, natural colouring matter and by-products of fermentation	0·85 " "

The mineral matter contains iron equivalent to 0·05 per cent. (as Fe_2O_3) of the extractives. Colouring matter not natural to a red wine was tested for with negative results. It is unfortified.

This is a natural and attractive wine of the Burgundy type. It may be described as rich to the palate, and the aroma is good. The low content of sugar will no doubt be appreciated by those whose sugar tolerance is below the normal. The amount of iron present adds to the tonic value of the wine.

THE LANCET.

LONDON: SATURDAY, JANUARY 2, 1932.

OUT-PATIENT FINANCE.

THE year 1932, which may test severely the principles of voluntary hospital finance, should see a speeding-up in the long overdue reform of the overcrowded out-patient department. At the present time nearly 4½ million new out-patients attend during the year at hospitals in England and Wales, and, while in the last decade the number of such new patients in London has increased by 10 per cent., the number of attendances has increased by nearly three times that percentage. It was expected that general practitioner service under the National Health Insurance Acts would gradually deplete the out-patient department; there was in fact a drop but only a temporary one, and the effect can no longer be discerned. Moreover, the recent approved society valuation shows that there will be less money available for additional benefits, which must now be cut down all round, and altogether discontinued in the case of 61 per cent. of insured women. The Hospitals Year Book calculates that the individual out-patient costs about 6*s.* 8*d.* It is not difficult to see that this little cumulative item may be the last straw that breaks a hospital's solvency, and we note with sympathy that the governors of the Newcastle Royal Infirmary have decided to limit the casual and out-patient departments of that great voluntary hospital to consultative work and to services of a special nature which are not available elsewhere.

In London where, so far, the more suggestions that are made for changing the out-patient hall the more the department remains the same thing, a small but significant proposal comes from without. The Hospital Saving Association, numbering close on a million members, would like to secure for them, on payment of a guinea, the right of seeing a consultant or specialist at his private house by appointment, instead of waiting to see him at hospital. Approach was made in the first instance to the head office of the British Medical Association which secured the general approval of its representative body, subject to acceptance of a scheme by a meeting of the consultants concerned. This meeting was held on Dec. 10th and decided by a substantial majority to draw up a list of physicians, surgeons, gynæcologists, dermatologists, oto-rhino-laryngologists, and consultants in physical medicine willing to see and advise at a modified fee members of the Hospital Saving Association and others of like economic status. It was said at this meeting that the Royal College of Physicians of London raised no objection to the principle of such mass consultations at a reduced fee, although Lord DAWSON expressed his personal conviction that in the long run no satisfactory service of the kind could be given outside the four walls of an institution.

This view of consultation as team-work has been growing in cogency ever since its first enunciation in the Dawson Report (Interim Report of the Consultative Council on Medical and Allied Services. Ministry of Health. 1920), and it is set out again in Dr. A. R. FRIEL's letter on p. 55. At one stage or another in most chronic illness a point is reached when some review of diagnosis or treatment or some pooling of information is desirable, which is outside the daily round of the most versatile individual practitioner. It is recognition of this fact that has filled the out-patient departments of teaching hospitals—for these deal with more than a third of the out-patients in the whole country—and has kept them full in spite of all the work of almoners and all the good intentions to carry out the recommendations of the committee appointed by King Edward's Hospital Fund for London 20 years ago. A good half of the out-patients now are believed to be consultation cases, and who would contend that the need for consultation is even yet fully met? The King's Fund raises the question whether out-patient departments should not be used only for purposes of consultation. That is one of the questions which has been remitted for consideration to a new committee of inquiry, of which the medical members are Sir JOHN ROSE BRADFORD and Dr. F. E. FREMANTLE. They will have to consider the possible relief afforded by other public medical services—including those taken over from the poor-law, and by a full use of general practitioner treatment, also bearing in mind what a large proportion of the population now contracts for hospital treatment by contributory associations. They will have to meet the oft-repeated claim that hospital out-patient departments are competing unfairly with the practitioner. Economic stringency is taking these matters out of the region of leisurely academic discussion into one of practical urgency. It may be, as the management committee of the King's Fund suggests, that the search for a solution of the out-patient problem may open up even wider questions than it did in 1911. But the solution must be found, and found quickly, if the voluntary hospital principle is to survive in the form we now have it.

THE LANCET.

LONDON: SATURDAY, JANUARY 2, 1932.

OUT-PATIENT FINANCE.

THE year 1932, which may test severely the rinciples of voluntary hospital finance, should see a speeding-up in the long overdue reform of the overcrowded out-patient department. At the present time nearly 4½ million new out-patients attend during the year at hospitals in England and Wales, and, while in the last decade the number of such new patients in London has increased by 10 per cent., the number of attendances has increased by nearly three times that percentage. It was expected that general practitioner service under the National Health Insurance Acts would gradually deplete the out-patient department; there was in fact a drop but only a temporary one, and the effect can no longer be discerned. Moreover, the recent approved society valuation shows that there will be less money available for additional benefits, which must now be cut down all round, and altogether discontinued in the case of 61 per cent. of insured women. The Hospitals Year Book calculates that the individual out-patient costs about 6*s.* 8*d.* It is not difficult to see that this little cumulative item may be the last straw that breaks a hospital's solvency, and we note with sympathy that the governors of the Newcastle Royal Infirmary have decided to limit the casual and out-patient departments of that great voluntary hospital to consultative work and to services of a special nature which are not available elsewhere.

In London where, so far, the more suggestions that are made for changing the out-patient hall the more the department remains the same thing, a small but significant proposal comes from without. The Hospital Saving Association, numbering close on a million members, would like to secure for them, on payment of a guinea, the right of seeing a consultant or specialist at his private house by appointment, instead of waiting to see him at hospital. Approach was made in the first instance to the head office of the British Medical Association which secured the general approval of its representative body, subject to acceptance of a scheme by a meeting of the consultants concerned. This meeting was held on Dec. 10th and decided by a substantial majority to draw up a list of physicians, surgeons, gynæcologists, dermatologists, oto-rhino-laryngologists, and consultants in physical medicine willing to see and advise at a modified fee members of the Hospital Saving Association and others of like economic status. It was said at this meeting that the Royal College of Physicians of London raised no objection to the principle of such mass consultations at a reduced fee, although Lord DAWSON expressed his personal conviction that in the long run no satisfactory service of the kind could be given outside the four walls of an institution.

This view of consultation as team-work has been growing in cogency ever since its first enunciation in the Dawson Report (Interim Report of the Consultative Council on Medical and Allied Services. Ministry of Health. 1920), and it is set out again in Dr. A. R. FRIEL's letter on p. 55. At one stage or another in most chronic illness a point is reached when some review of diagnosis or treatment or some pooling of information is desirable, which is outside the daily round of the most versatile individual practitioner. It is recognition of this fact that has filled the out-patient departments of teaching hospitals—for these deal with more than a third of the out-patients in the whole country—and has kept them full in spite of all the work of almoners and all the good intentions to carry out the recommendations of the committee appointed by King Edward's Hospital Fund for London 20 years ago. A good half of the out-patients now are believed to be consultation cases, and who would contend that the need for consultation is even yet fully met? The King's Fund raises the question whether out-patient departments should not be used only for purposes of consultation. That is one of the questions which has been remitted for consideration to a new committee of inquiry, of which the medical members are Sir JOHN ROSE BRADFORD and Dr. F. E. FREMANTLE. They will have to consider the possible relief afforded by other public medical services—including those taken over from the poor-law, and by a full use of general practitioner treatment, also bearing in mind what a large proportion of the population now contracts for hospital treatment by contributory associations. They will have to meet the oft-repeated claim that hospital out-patient departments are competing unfairly with the practitioner. Economic stringency is taking these matters out of the region of leisurely academic discussion into one of practical urgency. It may be, as the management committee of the King's Fund suggests, that the search for a solution of the out-patient problem may open up even wider questions than it did in 1911. But the solution must be found, and found quickly, if the voluntary hospital principle is to survive in the form we now have it.

GASTRIC HYDROCHLORIC ACID.

THE exact part which the gastric hydrochloric acid plays in the bodily economy is still in some respects unexplained. The secretion has of course a definitely bactericidal action which may be of great importance; at the same time it is certain that some people go through life without producing any hydrochloric acid, yet suffer from no dyspeptic or general symptoms. In others, it is true, an absence of hydrochloric acid in the stomach is associated with diarrhœa, which may be partly due to the passage of living organisms through the stomach into the intestine. But this diarrhœa may alternatively be ascribed to rapid emptying of the stomach, such as is commonly found with achlorhydria, and the consequent entrance of irritating and partly broken-up foodstuffs into the duodenum; and it is noteworthy that similar diarrhœa sometimes develops after gastro-enterostomy, although the hydrochloric acid secretion may be normal.

It has always been thought that the emptying time of the stomach is in some way associated with the acid secretion, and as long ago as 1907 W. B. CANNON definitely formulated the theory of the "acid control" of the pylorus, according to which the pyloric sphincter remains closed while the duodenal contents are acid, and opens when they become alkaline. Such chemical control by means of the gastric acidity was soon found incapable of explaining the whole mechanism of stomach evacuation, and other explanations were sought. J. EARL THOMAS[1] now suggests that the regulation is by stimuli both from the stomach and from the small intestine. Hydrochloric acid as such appears to play quite a minor part in governing the opening and closure of the pylorus, and THOMAS thinks that various factors are able, reflexly from the duodenum, to delay gastric evacuation by increasing the tone of the pylorus and inhibiting the motor activity of the pars pylorica. Of these factors, acidity may be one, but products of digestion (especially of fat) are others. As we noted not long ago,[2] the entrance of oil into the duodenum is capable of inhibiting both motor and secretory activity of the stomach, and THOMAS also records prolonged inhibition of the pars pylorica after introduction of fat into the duodenum, though only after quite a considerable latent period. There can no longer be any doubt that it is not the reaction alone, on either side of the pylorus, which governs the opening or closing of this sphincter, and the presence of hydrochloric acid is not necessary for normal gastric evacuation. Since neither the function of the gastric acid as a bactericide or as a regulator of pyloric activity appears to be essential, it has been suggested that its primary "purpose" may be to maintain the acid-base equilibrium of the body; that is to say, it is held that the stomach may behave somewhat like the kidneys and lungs, and excrete acid when the hydrogen-ion concentration of the tissues tends to shift to the acid side. Viewed in this light, the hydrochloric acid of the stomach would be an excretion—much as carbon dioxide in the lungs or acid phosphate in the urine are excretions—and its output would vary according to the condition of the body as a whole, rather than according to any conditions within the stomach itself.

F. L. APPERLY and M. C. CRABTREE,[3] without in any way entering into the discussion of such a theory, have lately recorded some experiments which suggest that the condition of the blood largely determines the secretion of hydrochloric acid and the emptying time of the stomach. They have studied gastric acidity by means of fractional gruel test-meals under varying conditions of plasma bicarbonate and blood reaction—i.e., in experimental conditions of alkalosis and acidosis similar to those occurring, for example, at high altitudes, or in diabetes. From their results in a number of ingenious experiments they conclude that the bicarbonate content of the blood plasma determines the concentration of the gastric hydrochloric acid during a fractional test-meal, and that the emptying time of the stomach is determined by the hydrogen-ion concentration of the blood. Such conclusions support the suggestion that the gastric mucous membrane may be an important regulator of the body's neutrality mechanism, and that gastric acidity is partly an expression of the reaction of the body as a whole. It would, for instance, be interesting to know the output of hydrochloric acid into the stomach after heavy exercise when "acid" is being excreted in large amounts in the urine and breath. To take another example, it may be that the achlorhydria found so commonly in fevers is not due, as K. FABER believes, to an endogenous or blood-borne gastritis from circulating toxins, but merely to relative excess of bicarbonate in the blood owing to over-breathing (hyperpnœa) and washing-out of alveolar carbon dioxide—a condition comparable to the hyperpnœa produced by immersion in a hot bath, in which APPERLY and CRABTREE found a diminished acid secretion of the stomach. Very broadly speaking, it may be that the more acid the body tends to become, the more hydrochloric acid will the stomach excrete, and the more alkaline the body, the less acid will the stomach put out, thereby maintaining the normal reaction of the tissues. If such views and observations were correct the question of gastric hydrochloric acid would assume a new significance, and R. BALINT'S treatment of gastric ulcer, by giving sodium bicarbonate intravenously and not by mouth, would be justified in theory. Hyperacidity would then become a question of an acid constitution rather than an over-acid stomach.

◆

RADIOPELVIMETRY.

IN his recent review of the work of the Rotunda Hospital[1] Dr. BETHEL SOLOMONS remarked that he believed the best results in pelvimetry were to be obtained by radiographic methods. Experiments along these lines were made in the very early days of radiology but were abandoned when the dangers of X rays became apparent, and gynæcologists have only recently found courage to resume them. At the present time there is no danger to mother or child. The technique employed does not vary very much, and is modelled on that devised by H. THOMS. The essential requirements are to place the patient in such a position that the brim of the s is horizontal above the film, to obtain a radiogram of the pelvic brim, and to correct measurements on the film for the distortion ting from the projection of the skeleton by rging rays on to a flat surface. Dr. L. A. DEN[2] describes a procedure that should offer ifficulty to any radiologist who wants to adopt The crucial point in all variations of the method ie correction of the distortion of the shadow, this is performed by almost every worker with variety of what Dr. Rowden calls a "pubic ." As part of his equipment, the radiologist ares a series of radiograms of a flat strip of lead ugh which have been punched a series of holes tly half an inch (or one centimetre) apart; essive films are exposed with this "ruler" sus-led in a horizontal plane at a series of distances ve the Potter-Bucky diaphragm corresponding the possible range of height of the symphysis is—in Dr. Rowden's practice at intervals of uarter of an inch from 4¾ in. to 6 in. The r is long enough to span the bony shadow, and s obvious that, since its image is distorted xact correspondence with the image of the is, it is an accurate scale by which to measure latter. Other workers use a steel strip with hes at each eighth of an inch, supported on patient's thighs during the exposure, and a nement used by Dr. H. J. Walton[3] is a chart le up from readings taken with his "false timetre scale" at various heights.

[3] Jour. Physiol., 1931, lxxiii., 331.

[1] See THE LANCET, 1931, ii., 1240.

n every variety of technique the patient is placed ted at the end of a table on the Potter-Bucky phragm, with her back supported by a rest lined at an angle of about 55°. Dr. Rowden ocates the use of a motor-driven Sectogrid phragm, and places the patient with the centre her pelvis above the central ball-bearing of the pliance; Dr. Walton is content with a Potter-cky of the ordinary type. Dr. Rowden demands ube-film distance of not less than 4 ft. 6 in.; greater accuracy secured by the use of this tance must be paid for in the correspondingly ater load which it is necessary to put on the be. He finds it necessary to expose the posterior rtion of the pelvis twice as long (or more) again the anterior portion, which he shades off during second part of the exposure with an implement ich he terms a "hatchet"—a sandwich of lead tween two pieces of three-ply wood mounted on handle, in shape something like a wooden fives-t with a large bite taken out of the far end. . Walton, possibly because he is content with 30-inch tube-film distance, does not consider is double exposure necessary, nor does he use a umb-line. Dr. Rowden's radiograms show the adow due to the ball-bearing of the Sectogrid aphragm and representing, of course, the normal ntral ray; its position may possibly serve as a ide to the amount of uncompensated distortion the edges of the film. After the exposure, the ight of the top of the symphysis pubis is measured: r. Walton takes the height to the film, but Dr. owden takes it to the diaphragm, fearing to introduce extra errors. Dr. Rowden claims to be able to measure this distance to within a quarter of an inch with callipers. The pubic scale corresponding to the measured height is attached to the film, and the measurements taken against it with callipers. Dr. Julius Jarcho,[4] another American worker, verifies the position of the inlet by measuring the distance between the spine of the fifth lumbar vertebra (marked with an adhesive tab) and the film, and the distance between the top of the symphysis and the film: the latter measurement is obtained by means of a plumb-bob attached to a support near the tube. After the patient has been radiographed, a second exposure is made on the same film through a thin lead plate punched full of small holes at intervals of exactly one centimetre, held on an adjustable stand in the same position as the plane of the inlet occupied before. Dr. Jarcho recommends an increase in the exposure corresponding to the degree of obesity of the patient and the amount of hydramnios. He also lays stress on the value of lateral pelvimetry for detecting disproportion between the fœtus and the outlet.

From the theoretical point of view, of course, these methods are open to the objection that the pelvic opening is not all in one plane. Moreover, unless the brim is quite parallel to the plate, a considerable error may creep in from the inclination of the true conjugate to the horizontal. Dr. A. Orley, in discussing Dr. Rowden's paper when it was delivered, pointed this out, and also that, as the transverse and antero-posterior diameters of the pelvis lie in different planes, they cannot be measured by a single projection. He measures the heights of the top of the symphysis and of the spine of the fourth lumbar vertebra (not the fifth, as in Dr. Jarcho's method), and the height of the postero-superior spine of the ilium; having radiographed the patient he superimposes two images of a perforated lead plate, one in the plane of the antero-posterior diameter and the other in that of the transverse diameter, the lead plate being turned through a right angle for the second exposure.

Measurements made by these methods are widely regarded as more accurate than the result of any clinical estimation. When, however, radiography is applied to the measurements of the fœtal cranium, there is room for some doubt, although if the radiographic examination is made within a fortnight of term the relative size of head and brim can be relatively gauged. Dr. Rowden gauges the size of the head by its probable distance above the brim, and Dr. Walton makes two exposures at right angles, in the antero-posterior and lateral positions, centring on the head as located by manual or radiographic examination, a method which is open to question as errors must produce distortion. Dr. Jarcho's use of adhesive marks and the pelvimeter sounds as though it should locate the centre of the head with as much precision as any other method. The obvious difficulty is always that small errors are easily magnified. Nevertheless, it is probable that radiology will be increasingly used for pelvic measurement, and also for the diagnosis of multiple pregnancy, monstrosity, and fœtal death, in which it has already shown its value. Under favourable conditions a positive diagnosis of pregnancy can be made radiographically from the third month.

"THE LITERATURE."

A SIGN of the times is the growth of an immense literature (so-called) at every point where scientific progress is being made. The evolutionary function designed by the producers is, doubtless, the formation of a base from which further to invade the unknown, and in so far as the granulation tissues of information are convertible into the permanent structure of knowledge, the writings satisfactorily serve this purpose. But one cannot help thinking that nowadays the proliferation has become a little pathological—a little malignant. Research workers, teachers, and learners are only too likely to waste their vitality in forcing their way through the unorganised masses of facts and fancies produced by those in front, and in all departments people are beginning to feel that they cannot cope with the task of being well-informed, even about their own subject. The conscientious teacher has the additional discomfort of feeling himself a humbug because his students assume that he is conversant with all the newest developments, whereas in reality it is quite impossible that he should be.

Any attempt to check the output of writing at its source must aim at removing its psychological causes, which are chiefly connected with the competition for priority and prestige, and the livelihood they may ensure. There is no doubt that if the problem could be attacked from this point it would be largely solved, for no one can fail to see that an enormous amount of work is prematurely published or purely repetitive. But a radical change of this kind is out of the question at present, and attention must be mainly directed to the devising of expedients whereby those new facts which are valuable are sorted out and made accessible to the specialist workers concerned. The three chief forms in which the material thus collected is given out again to those who need it may be classified as the tome, the review, and the abstract. Of these the two last are usually periodical at comparatively short intervals, while the first is only periodical at long intervals, in the form of new editions, or not at all. The tome thus rapidly becomes out of date—a criticism which we made a short time ago in reviewing a large new monograph on the vitamins, which is typical of the tome class. The tome may or may not be critically written; in proportion as it is critical and as the criticism is sound the book becomes more valuable. On the whole, however, it is in the two periodical forms that the greatest help is to be found. The review is critical, and selects for notice at regular intervals the salient advances made in the preceding interim period; but unfortunately this period may be of considerable length—even a year or two—so that there is a certain lag which is important to the research worker though less so to the teacher or learner. If edited with a sound critical judgment and power of selection the review should be the great standby of the teacher and the learner, and we are glad to notice that another periodical of this kind, the *Annual Review of Biochemistry,* is promised early next year. The panel of reviewers includes very distinguished names.

Finally, as we have said, the literature of a subject may be dealt with by means of the journal of abstracts, which is comparatively non-critical and essentially non-selective. It aims at being as complete as possible, and in appearing with as small a time-lag as possible; and though it is not outspoken in criticism, it is bound to develop subtle ways in which useful criticism can be conveyed, chiefly by a manipulation of phrases and by varying the amount of space devoted to particular pieces of work. Obviously it is as useful a function of a journal of abstracts to indicate to its readers which papers are not worth referring to in extenso as it is to make accessible to them brief and clear accounts of those which are—provided that the treatment is fair and broad-minded. The first number of such a publication has just appeared under the title of *Nutrition Abstracts and Reviews.* It is to be issued quarterly, but the first number is a double one, representing abstracts of papers which came out in the first six months of 1931. The delay in the appearance of the abstract of any given paper was therefore anything from five to eleven months, but it is hoped that when the journal has got into its regular swing this delay will be reduced to three to six months. The journal is sponsored by a committee of management representing the Imperial Agricultural Bureaux Council, the Medical Research Council, and the Reid Library, while the editorial staff is drawn from the Imperial Bureau of Animal Nutrition and the University of Aberdeen. The vitamin section is edited at the Lister Institute. The first number contains three excellent reviews on general aspects of nutrition by Sir GOWLAND HOPKINS, Prof. E. P. CATHCART, and Dr. J. B. ORR. The abstracts cover a very wide field, and make available work in a great number of journals to which the ordinary investigator has no access. Unimportant papers are noticed as briefly as possible, and the whole publication should achieve the aim of relieving the nutritional worker of an intolerable burden.

COMPENSATION TO A HOSPITAL.—The corporation of Bath having, under a local Act, taken compulsorily certain property of St. John's Hospital, a question arose as to the method of calculating the compensation, which was to be a capital sum which at 4 per cent. per annum would produce an amount equal to the average net annual income which would have been derived but for the passing of the Act. Upon a special case stated by the arbitrators, Mr. Justice Wright, in the King's Bench division, fixed the compensation at £26,875.

ANNOTATIONS

FOOD POISONING BY STAPHYLOCOCCI.

NTIL a few years ago the only bacilli conclusively ɣn to be associated with food-poisoning outbreaks ɜ organisms of the salmonella group and *Bacillus linus* in its several types. Others, such as *oli* and *B. proteus*, have been advanced to explain vidual outbreaks, but while their claims cannot lecisively refuted for every outbreak the evidence iminating them is always open to doubt and is n valueless. The prevalence of particular types ɔoisoning varies to some extent with locality, for le botulism outbreaks have usually been confined he Continent of Europe and to the United States merica, with only one recorded outbreak in Great tain, the ordinary form of food-poisoning in this ntry is due to salmonella, which is less common the U.S.A. It was to be anticipated that other terial types might cause similar attacks, and ly evidence has accumulated that certain strains staphylococci may do so. In view of their wide ribution in nature such a possibility deserves eful consideration.

n an outbreak of acute gastro-enteritis due to k in 1914 in the Philippines, M. A. Barber found the milk a white staphylococcus derived from the ler of a cow. He inoculated sterile milk with a e culture, incubated it for eight and a half hours l drank 50 c.cm. Two hours later he began an ack of gastro-enteritis, and next day he recovered. December, 1929, the consumption of a Christmas nge cake caused 11 cases of food-poisoning in icago, and G. M. Dack and co-workers[1] who investi-ted the outbreak found a yellow hæmolytic phylococcus in large numbers in the cake. This itself was not conclusive, but when the organism s grown in broth for 40 hours and filtered, 25 c.cm. the sterile filtrate produced a typical attack in a man volunteer, while smaller doses (5 and 10 c.cm. pectively) in two other volunteers produced only ght discomfort. This work was carried out in the icago University bacteriology department, and of. E. O. Jordan studied the possibility of other ains of hæmolytic staphylococci being able to oduce toxic substances. Fortunately he had abund-ce of human volunteers (about 58), and some 80 ding tests were carried out with sterile filtrates. ost of the staphylococci tested had toxigenic operties, including three from normal human roats and three from food implicated in food-isoning outbreaks. Filtrates from 48-hour cultures ere as toxic as those from seven-day cultures and e symptoms were often severe, but recovery was ways prompt and complete. A third outbreak is w described by Jordan[2] associated with cheese Porto Rica. From this he isolated a yellow aphylococcus, and filtrates of broth cultures repro-uced the symptoms of food-poisoning in three uman volunteers. With J. R. Hall[3] he has reported fourth outbreak in which a man and his wife eveloped severe symptoms about three hours after meal in which the peccant food was chicken gravy. culture of the *Staphylococcus aureus* type was olated, and filtrates of pure cultures reproduced he symptoms in four out of six human volunteers nd with an incubation period of about three hours. Lastly, in his latest paper,[2] he gives details of five other outbreaks, in one of which the ætiological association was proved by the employment of human volunteers, while in the other four the evidence was suggestive, but similar proof was not forthcoming.

This important series of investigations, mostly emanating from the Chicago University bacteriology department, has clearly demonstrated that certain staphylococci must be accepted as causing food-poisoning. The symptoms are of the gastro-intestinal type, the incubation period is short (two to four hours), and so far no deaths have been recorded. On the bacteriological side Jordan remarks that these staphylococci "do not seem to differ in their main cultural characteristics from the common and widely distributed members of this group. Both *albus* and *aureus* varieties are found among the strains yielding toxic filtrates." The human experiments show that the sterile filtrates are toxic. The resistance to heat of this toxin is of no little practical importance, and the earlier evidence was to the effect that it was destroyed by boiling and weakened at lower temperatures (60 to 65° C.). More recently, however, Jordan, Dack, and O. Woolpert[4] have revised this opinion, and conclude that the toxic substance is not completely destroyed by exposure for 30 minutes to the temperature of boiling water. This point cannot be considered settled. It is one of some difficulty, for the lower animals, even monkeys, have proved unhelpful in this work. Results can be satisfactorily obtained only by the use of human volunteers, and the experiments so far carried out show that individual susceptibility is variable. The question arises whether artificial protection is possible, and the last-named workers have attempted to immunise human volunteers with these toxic staphylococcus filtrates.[5] Some degree of tolerance appeared to develop, but there was no sign of the formation of any true immune bodies. Repeated attacks of gastro-intestinal disturbance may be produced in the same person by successive feedings.

We congratulate the Chicago school upon a series of brilliant investigations, and upon the recognition of another bacterial cause of food-poisoning—one which may in future explain a number of outbreaks whose cause would otherwise be obscure. While unable to repress our envy at the opportunities for experimental work, we must offer full meed of praise to the long tale of human volunteers (over 100) who have so willingly poisoned themselves with staphylococcal filtrates.

BACTERIOLOGY OF RHEUMATOID ARTHRITIS.

THE appearance, at fairly regular intervals, and more frequently in America than elsewhere, of papers relating streptococcal infection to polyarthritis emphasises the fact that most bacteriologists fail to reproduce the successful findings of the few. The relative ease of procuring positive blood cultures in malignant endocarditis, and even of growing gonococci from cases of gonococcal arthritis, contrasts with the negative findings which are the lot of most routine workers in the culture of blood and joint exudates in the disease variously known as polyarthritis, rheumatoid arthritis, and arthritis deformans. However, one positive result is worth a dozen negatives;

and the claims made deserve serious consideration. The work of Cecil and his co-workers[1] attracted attention to points of technique; in particular the long period allowed for the development of positive cultures (up to one month) and the frequent subcultures were open to criticism, since contamination was to be suspected. Cecil claimed positive findings in 62·3 per cent. of cases. The question obviously resolves itself into one of technique, and it has been reopened by a paper from the arthritis clinic of St. Barnabas, New Jersey, by Gray and Gowen.[2] They modified Cecil's method slightly, with the surprising result that cultures were found to be positive, in much the same percentage of cases, but within one to four days, instead of a month. The essential feature of Cecil's technique was the culture of blood clots, separated from the serum and its inhibitory elements. The modifications consist of the addition of gelatin "to create oxygen tension," calcium carbonate, and glucose. Armchair criticism would admit that clot culture might well succeed, since serum is undoubtedly inhibitory, and the successful culture of blood in distilled water is due to its dilution. Beef broth contains about 0·2 per cent. of glucose; the calcium carbonate is merely a buffer, and gelatin is not traditionally used for modification of the oxidation potential of fluids, which is more readily achieved by glutathione. Prima facie, the change would not be expected to produce the startling acceleration of positive results with which it is credited.

The organism is said to be a streptococcus of *viridans* or α-hæmolytic type, producing green discoloration on blood media. Therapeutic results with vaccines are stated to be remarkably good. Of the 48 cases cited in the protocol all were bettered, the remarks varying from "astonishing improvement," through "cured" to "improved." Certain results, however, require explanation. Astonishingly high agglutination titres are claimed from the blood of infected cases; up to 1 in 5120. Such a titre would be outstanding even in an experimental animal, and no details are given of the technique used and how auto-agglutination—the bane of streptococcal agglutination—was overcome. Moreover, the paper seems too rich in negative controls, 106 in all. The streptococcal theory of arthritis goes hand in hand with "focal sepsis," and some of the cases of chronic sinusitis and chronic tonsillitis should have given positive results. Incidentally, 17 cases of osteoarthritis were negative.

There are two aspects of rheumatoid arthritis, both of the utmost importance, but quite independent of each other. For ætiology and therapeutics are, unfortunately, not yet inevitably associated. Vaccine therapy is going through a lean time, and streptococcal vaccines in general are failing to commend themselves. The tendency of rheumatoid arthritis to spontaneous amelioration is well known; it is a disease of exacerbations; often it runs an acute course and is not progressive after its early mutilating crisis. If the 48 cases of amelioration were attributable to the vaccine they have little analogy with vaccine therapy in general. Cultural experiments, however, deserve and will doubtless receive careful consideration. Full technical details are given in this paper, and the claim of the authors in support of Cecil's work can easily be confirmed or repudiated. It is to be hoped that the investigation will be repeated in t country.

A NEGLECTED MEDICO-LEGAL PROBLEM.

THE fugue described by Dr. Chambers and Dr. Harrowes elsewhere in this issue recalls N. Vinci's recent account[1] of loss of personality in a boy of 12 whose case was remarkable in that the memories of his lost self could be minutely recalled under hypnosis. but for some months did not enter the waking consciousness. It is obvious that modern psychological technique can be applied to these cases both for therapeutic purposes and to establish their genuine nature, and in face of the numerous cases of "loss of memory" that are reported in our newspaper this fact should be more widely known. The con dition is one that cannot be diagnosed in the absenc of expert examination, and an instructive note i the account of the Perth case is the difficulty i convincing the police that the case was genuin Their conversion is described by the writers, and the patient had *actually committed some* breac of the law the evidence of the two psychiatrists migl have been sufficient to protect him from punishmei while he was still in a fugue state. There can l little doubt that such a fate befell the victim of tl case at Hove that aroused protests in our corr spondence columns last August, and it appears us discreditable to the professions of law a medicine that there is no security that similar cas will receive the skilled attention that happened be available for this one fortunate sufferer.

ÆTIOLOGY AND TREATMENT OF WHOOPIN COUGH.

WHOOPING-COUGH has long defied both bacter logists and clinicians. The former do not definite agree about the precise nature of the causal agent, while the latter are faced with difficulties in early diagnosis and have no accepted and effective plan of therapy. The paper by Dr. Gardner and Mr. Leslie, published at p. 9, is timely: first, because it emphasises the importance of the disease as a cause of infant mortality; and, secondly, because it contains bacteriological information not generally available. Since 1907, when Bordet and Gengou described a small Gram-negative bacillus now known as *Hæmophilus pertussis* in infected cases, there has been much controversy about the ætiological relationship of this organism to the disease. The difficulty has been its isolation and differentiation from Pfeiffer's bacillus. Some years ago, however, as Gardner and Leslie tell, Madsen and his colleagues in Denmark introduced the "cough-droplet method," whereby it can be isolated in as many as 75 per cent. of cases in the first week of the disease, and these results have been confirmed not only in England by Sugare and MacLeod, but also in America, where positive results up to 93 per cent. have been obtained in the early stages. This method ought to be much better known because of its value at the onset of the disease, before paroxysmal coughing begins; but even at this stage it must, of course, be remembered that a negative result is not conclusive. Moreover, at least three days must elapse before a positive result can be given, and Gardner and Leslie possibly underestimate the difficulty of bringing the test into general use outside large towns. As we have said already, only positive lts would be of value, and anyone who has ked at isolating *H. pertussis*, and knows the culties connected therewith, will appreciate the ıber of additional adverse factors which would ıe into play when such work was removed from immediate confines of a well-equipped laboratory. perience has also shown that it would not always easy to ensure that the plates returned had been cted in the proper manner during a natural ack of coughing, but this objection should not, course, arise where practitioners are able to ervise the taking of the culture. In the later ges of the disease, after about the third week, chances of finding the Bordet-Gengou bacillus extremely remote, and it appears that patients definitely non-infective after the sixth week. rdner and Leslie advocate the use of specific cines in prevention and cure, but here again must be borne in mind that the employment of cines in the prophylaxis and treatment of whooping-gh has so far shown little or no promise of success. bably the organisms used for these vaccines were and not in the correct antigenic phase, and haps further trials with recently isolated strains h the antigen in Phase I. will be more fruitful. nilar results to those of Gardner and Leslie have n obtained by W. A. McGee,[2] who has also con-ered the treatment of established cases of whooping-gh. He found that while ephedrine was more ful than the usual cough sedatives, rectal ether—t recommended by C. L. Elgood in England—gave tstanding results. The ether is administered with ual parts of olive oil (except to infants under one ar of age, who are given 25 per cent. ether in double sage), and the dose is 1 drachm per year of age, en twice daily through a soft rubber catheter. It claimed that freedom from severe paroxysms and miting may be obtained within a week.

THE INHERITANCE OF INTELLIGENCE.

Dr. Evelyn Lawrence has made a new contribution [3] the old controversy on nature versus nurture, r special problem being the relative importance of redity and environment in determining the level intelligence. For this purpose she has applied telligence tests to a considerable number of children awn from various institutions and schools, relating e results to the social class of the parents—a iterion of intelligence whose inadequacy she recog-ses. As regards the distribution of intelligence r observations are in keeping with those of previous vestigators. As we go down the social scale from e higher to the lowest classes the intelligent quotient adually shifts over from above the 100 level to nsiderably below it. There has, however, been ttle clear evidence hitherto to explain how these fferences of level arise, how much they are due to herited differences, and how much to the immense vironmental differences. Dr. Lawrence finds a rrelation between the intelligence of children and e social class of their parents when they have never en those parents, but have been brought up in stitutional life. This is "fairly conclusive evidence," he says, "that the correlation so generally found r children in their own homes is not mainly due o the direct social influence of the home, but is a enuinely biological fact." On the other hand, the correlation she finds is by no means a high one—it is of the order of 0·2 to 0·3—so that inheritance is by no means necessarily the only, or even the dominating, factor. She herself concludes that the association is rather smaller in the case of institution children—the figures in support are not very convincing—and that "there is little doubt that environmental conditions have some weight in influencing the response to tests." A further test was made by the comparison of children taken away from home at an early age with those in the same institutions who were removed from their parents later in life. The figures suggest that the correlation between the child's intelligence and the social status of the parents is somewhat less among those who entered the institution earliest in life, but it is very doubtful if these differences are significant. They are not supported by the fact that the children taken from bad homes to institutions showed almost no increase of intelligence with the improvement of their surroundings. There was also little difference in variability between the children in the uniform environment of the institution and those in their own diverse homes, though if environment can affect intelligence scores we should certainly expect children reared in an institution to be more alike than those brought up in the widely varying surroundings outside. Various health-ratings, such as height-weight index and nutrition, were correlated with intelligence without significant result.

With such small correlations between intelligence of child and status of parents any generalisation about social classes is a hazardous business. Dr. Lawrence concludes that "for any definite plans for social reform based upon the differential inheritance of intelligence, social class is not a satisfactory grouping. Either some basis of classification resulting in more homogeneous and more widely differentiated groups needs to be found, or we must realise that the only safe unit by which to assess intelligence is the individual, or at most the family."

OCULAR PLUMBISM IN CHILDREN.

LEAD poisoning in children must be extremely rare in England, but in certain parts of Australia it is, it seems, not uncommon. Mr. J. Lockhart Gibson, consulting ophthalmologist to the Brisbane Hospital for Sick Children, who has been writing about this condition at intervals for the last 30 years, points out [1] that in Queensland houses are commonly built with verandas, whose railings are of wood, which, especially in the neighbourhood of towns, is usually painted with white lead paint. In that semi-tropical climate the sun soon converts this paint into a powdery substance which rubs off easily on the hands, and this has been found to be a soluble carbonate of lead. In the summer young children spend a large part of their time on the verandas, and Mr. Gibson observed that the children in the families who became affected with lead were generally in the habit of biting their nails or sucking their fingers. It may be remembered that in writing on the incidence of chronic nephritis among these children, L. J. J. Nye mentioned that there is a local pastime of licking the raindrops from the veranda railings.[2] Cases of wrist-drop and foot-drop were first described in Queensland children in 1892. Ever since 1897 Mr. Gibson has come across cases of paralysis or paresis of the external recti, combined with papillœdema, and this he regards as an early, and therefore important, sign of lead poisoning. In the early cases the child hardly appears to be ill, and the condition would be unrecognised by the parents were it not for the sudden and fortunate appearance of a squint. In severe cases the patients are so ill that they are confined to bed, and are thus removed from the further ingestion of lead, but damage to vision from post-papillœdemic atrophy may readily take place unless, he says, a timely lumbar puncture is done. These cases result from a comparatively large quantity of lead being ingested in a short time. The pathognomonic blue line on the gums and other typical symptoms do not have time to develop, but lead can be discovered in the urine. The cause being removed, the essential treatment in cases with papillœdema is a prompt lumbar puncture. If the intracranial pressure is in this way returned to normal sufficiently soon, recovery, in Mr. Gibson's experience, is certain; otherwise blindness may ensue. The ocular paralysis is always recovered from. He adds that a good substitute for white lead in paint is zinc white, which, he says, lasts longer on exposed surfaces.

OFFENSIVE BREATH.

HALITOSIS, as it is called politely, is one of those minor disorders that make life a misery. When aware of it the sufferer can easily develop serious depression and a painful sense of inferiority. To prevent such a misfortune the courteous Japanese, it is said, consider it good manners to inhale continuously through the mouth (like an inverted ostler) during propinquity with a stranger's breath; whereby they mean to imply that nothing could be sweeter. Even we, in relatively barbarian lands, will suffer much before mentioning fœtor oris to our friends, and often perhaps this is kind only to be cruel. The medical practitioner, at any rate, should be very ready to consider and deal effectively with any such disability encountered in a patient, and he must certainly be the last to dismiss it as trivial because the cause is not apparent. First he will probably, and rightly, think of the mouth, and it is interesting to find that H. Prinz,[1] reviewing the subject as a dentist, attributes offensive breath in at least 90 per cent. of all cases, to prolonged stagnation of food debris about the teeth. Both carbohydrate and protein may undergo decomposition in cavities and crevices around the teeth, and any actual pyorrhœa or exposed gangrenous tooth pulp increases the odour. That food debris alone is often responsible is shown by the fact that artificial dentures which are not kept perfectly clean may become quite definitely offensive though their owners are edentulous and have no gingivitis. Wherever, therefore, there is bad breath most careful search is necessary for evidence of dental sepsis or carelessness in removal of food debris by frequent cleaning—though there is always a danger that vigorous brushing with a hard brush may damage the gums and allow organisms to enter the tooth margins.

After the teeth the next commonest source of fœtor oris is probably chronic pharyngitis and tonsillitis. The tonsils may appear normal on superficial examination, but more thorough search may reveal crypts containing cheesy and highly offensive material which is the cause of the smell. This is a very important condition which may only respond to tonsillectomy, though local application of silver nitrate to the crypts is some effective. Chronic sinusitis is more usually productive of a bad taste noticed by the patient himself than of any marked fœtor in his breath; atrophic rhinitis or ozæna is, of course, a recognised though luckily rare, disease in which the breath is particularly foul. Informed opinion has i that digestive disorders less often cause offensive breath than might be expected—gas brought up from the stomach directly by belching is usually odourless, but may sometimes have a smell of fermentative fatty acids or hydrogen sulphide. This, however, is the smell of flatulence and not of ordinary breathing. Quite different is the origin of substances absorbed from the intestinal tract and excreted by the lungs, but with experience of onions and alcohol, it is easy to imagine that tainted breath is very often due to alimentary putrefaction. Thus, it is generally believed that constipation is pretty commonly responsible. But those best qualified to judge seem to think that the products of abnormal bacterial fermentation seldom travel from the colon to the breath unless there is actual disease of the mucous membrane. Constipation, they say, is not often to be blamed for offensive breath, notwithstanding the widespread belief to the contrary; enteritis is a more frequent cause than colitis, gastritis—in the absence of pyloric stenosis—less common than either.

There is no need here to do more than mention the kinds of offensive breath encountered in chronic pulmonary disease, the characteristic smells associated with uræmia, and diabetes, or the odours said to be recognisable in certain fevers and—especially by animals—when death is imminent. The problem with which we are concerned is the problem of the ambulant man, woman, or child whose trouble may be a source of much distress. In far the greatest number of such cases fœtor oris has its origin in the teeth, tonsils, nasopharynx, or respiratory tract in only a relatively small proportion is it traceable to metabolic or digestive disorders. Treatment and prevention must thus mainly be directed to the local conditions around the oral cavity, and it is correspondingly unwise to begin by concentrating one's attack on liver and bowels.

HUNGER AND THE NERVOUS CHILD.

THAT nervousness in elementary school-childre is definitely related to hunger and diet is the conclusion of D. A. Laird, M. Levitan, and V. A. Wilso who describe their investigation in a preliminary repo dealing with certain groups of American school-children.[1] Recognising that the term "nervousness" describes a wide range of conditions and behaviour, they allowed the school-teachers to select those children regarded as the most nervous in the educationist's sense, and then measured their nervousness according to a "check list" described by W. C. Olson. The 53 children thus selected were free from all signs of malnutrition and obvious physical disorders. One group received half a pint of milk at 9.30 every morning for five days each week, this time being selected because it was found that few of them had much breakfast and that even when this was at all adequate it had usually been taken at 7 so that the stomach was empty by 9.30. In another group a food concentrate was added to the milk to supply extra calcium so that at least one gramme of calcium was obtained daily—this being regarded as the minimal require-t of the growing child. The food concentrate contained vitamin D and phosphorus, since these ; considered essential for the utilisation of calcium, lactose instead of cane sugar was used as a tening agent because it is believed to facilitate ıbsorption of the mineral. A group of ten nervous lren received no extra nourishment, merely ing the class-rooms with the others and being to play with toys until it was time to return ther. Although closely coöperating in the work, teachers were kept in ignorance of the procedure : the children had left the class-rooms, and they not know which of them received special diets. y were thus in a position to judge the results. control group showed an improvement of just : 2 per cent. in nervousnesss at the end of a two-k period, as measured by the check list, possibly ıuse of the personal attention given them. Those iving the extra milk showed an 8 per cent. improve-.t, but in three directions the improvement was ıuch as 25 per cent.—i.e., they were to this extent easily fatigued, more even-tempered, and less ommunicative. Those receiving the food con-trate in addition to the milk showed an average rovement of over 15 per cent. In discussing results the investigators claim that the success he milk feeding is due to the removal of hunger ıs, since the active peristalsis of the stomach ch takes place during hunger is liable to cause lessness and irritability. The influence of calcium n the activity of nerve and muscle is held to explain beneficial results of adding it to the diet. In a more oorate experiment lasting two months the food centrate was given for the second only of four nightly periods when milk was given. The rovement brought about during the calcium night was slowly lost after the calcium was omitted. rd and his colleagues think that the calcium tabolism needs to be attended to consistently her than sporadically. They hope that their ılts "may help to convince school board officers l others who are not yet convinced of the importance school lunches for children that the necessary ds be provided and neurosis in this class of children sened and possibly prevented."

W LIGHT ON POST-OPERATIVE ATELECTASIS.

POST-OPERATIVE atelectasis, though seldom fatal, y be the cause of severe distress to a patient who s not yet recovered from a severe laparotomy, and embarrassment to a surgeon who has just been ıgratulating himself on the success of a difficult eration. Its onset is usually preceded by bron-itis associated with the expectoration of viscid utum. The symptoms of an acute respiratory sis (dyspnœa and cyanosis) which follow are evi-ntly the result of a blockage of bronchi by accumu-ed secretion. As in other types of bronchial struction stagnant air in the lobe normally supplied the affected tubes is removed by way of the blood ream. At the same time the movements of the uscles of the chest wall and of the diaphragm are nited on the affected side, a disability formerly held be the cause and later commonly regarded as the sult of the underlying collapse. Dr. C. M. van llen [1] [2] now shows that both factors are concerned—ıat though restricted respiratory movements when ıe airway is patent do not result in atelectasis, a paresis of the diaphragm plays a not unimportant part in its production after abdominal operations.

There appears to be in the lungs a collateral air circulation analogous to the collateral circulation of the vascular system. Collateral air circulation is possible because the interlobular septa are incomplete and alveoli of neighbouring lobules communicate with each other by minute stomata. In van Allen's opinion, massive atelectasis is due to the association of bronchial blockage with failure of this collateral respiration. He holds that such a failure is often due to diaphragmatic inertia, and adduces three groups of experiments in support of his theory. During radiographic examination by means of a double exposure it is possible to record the position of the diaphragm in full inspiration and expiration, the amplitude of its movements being thus clearly shown on one film. A large series of films taken in this way showed abdominal section to be followed by considerable reduction of the range of excursions of the diaphragm, though there is only slight limitation of rib movements. There was no such limitation of movement after operation on the extremities, and we must therefore assume that trauma of the abdomen is a cause of feeble muscular action which may militate against adequate ventilation of the lung bases. A second series of experiments made on dogs proved that though deflation of a lobe follows ligature of the main bronchus supplying it, lobar collapse does not occur if the constriction is applied immediately distal to the first lateral branch. If this remains patent the collateral air circulation comes into play and air percolates from the area surrounding the branch through the rest of the lobe and maintains its expansion. The efficiency of the collateral respiration is dependent on the depth of breathing and is markedly diminished, for example, when the animal is deeply anæsthetised. A tight costal bandage does not hinder air circulation, for the diaphragm is not affected, but an abdominal binder firmly applied interferes with the movements of the midriff and decreases collateral circulation, while section of the phrenic nerves abolishes it. In a third series of experiments the stem bronchus of an accessory lobe was ligatured and the lobe became completely atelectatic. At the same time a ligature similar to that performed in the second series of experiments was applied to the stem bronchus of a lower lobe. In this lobe collateral circulation prevented collapse, though radiograms taken after the injection of lipiodol showed that there was effective bronchial obstruction in the area which had profited by the collateral aeration.

The conclusions drawn from careful experiment thus seem to warrant the belief that abdominal operations have an adverse effect on diaphragmatic movement and hence on the efficiency of collateral respiration. Plugging of bronchioles by tenacious phlegm would in these circumstances result in lobular atelectasis and an aggregation of lobules thus affected might produce lobar collapse. Such collapse also follows the plugging of a main bronchus, but in post-operative conditions this is presumably less likely. Van Allen believes that post-operative diaphragmatic inertia is due to reflex inhibition, the result of irritation of the lower intercostal nerves. This theory finds some support in the observation that a temporary elevation of the diaphragm sometimes follows injury to the chest wall; an example of such a sequence was recently described in our columns.[3]

[3] Wood, W. Burton, and Wood, Franklin G.: Congenital Elevation of the Diaphragm, THE LANCET, 1931, ii., 392.

Experimental stimulation of the distal ends of divided intercostal nerves has produced a similar condition. It seems unlikely that the pressure of an ordinary abdominal bandage would be sufficient to produce the effects obtained in dogs subjected to experimental abdominal pressure, and further investigation of this problem is proposed. Meanwhile, however, a practical deduction may be made. Post-operative atelectasis is associated with a sluggish action of the diaphragm. Deep-breathing exercises, by encouraging diaphragmatic excursion and the movements of the lower intercostal muscles, will tend to preserve the collateral respiration, and thus obviate the ill-effects of mucoid plugs in the bronchioles. Such exercises have already been practised in certain institutions, and their employment should be encouraged so far as the patient's condition and the nature of his wounds permit.

We welcome Dr. van Allen's observations all the more because they come unexpectedly from the distracted country of Manchuria, where he holds a chair of surgery. And we take this opportunity of wishing success to the new *Journal of Thoracic Surgery* in whose first number his principal paper appears.

PROGNOSIS OF DIABETES IN CHILDHOOD.

A GLOOMY picture of the future of the diabetic child is painted by L. Salomonsen,[1] who at the end of 1930 inquired into the fate of 68 children treated at the Rikshospital in Oslo between May, 1923, when insulin was first introduced, and December, 1927. Thirty-five were found to be dead, the cause of death being diabetic coma in 31 cases, and intercurrent disease in the other four. A classification of the children, according to duration of life after the institution of dietetic and insulin treatment, brought out the interesting fact that those who died did so *often after a comparatively short interval.* Only two of those who died had been ill for over four years, and many of the early deaths were clearly due to the inability of the parents to carry out the treatment prescribed. The ten children who, for one reason or another, were never given insulin, all died. Of the 38 children to whom insulin was given, but without adequate dieting or skilled medical supervision, 18 died. On the other hand, of the 20 children systematically kept under observation, with strict dieting and sustained insulin treatment, all but five survived, and in considering these figures it is important to remember that although insulin treatment began in 1923, it was for the first few years extremely restricted in every respect. Only very small amounts of insulin were given, and the diets were correspondingly small. Insufficient food matters far more to children than to adults, but during the last few years only has it been recognised that large doses of insulin which allow of diets sufficient for normal growth and activity must be given to diabetic children if they are to develop normally. When looking to the future we may ignore all the cases in Salomonsen's series except the last group of 20. And even here the mortality of 25 per cent. within four years is not at all what may reasonably be expected nowadays. The ability to use insulin to the best advantage is still increasing, and the death-rate should yet be much reduced. Two years ago we commented [2] on the more encouraging results obtained by E. P. Joslin at the Mayo Clinic, where 147 out of 164 cases treated since 1923 were still alive in 1928. A analysis of the cause of death in the 17 fatal cas showed that in eight of them insulin treatment w either not used or was suspended for one reason o another, while in four others the disease was allowe to get out of control. It is not too much to say th the future of the diabetic child is hopeful, in so far a insulin is used to the fullest advantage. In England at any rate, many of the older physicians in practice away from hospitals have necessarily had very litt experience of insulin, and so when the treatment o the *diabetic child is under discussion the question i* still frequently heard: Is it really worth it? Tho who have encountered some of the healthy happ diabetic children whose disease brings hardly an disability will probably answer, Yes. Pessimism wi gradually disappear with the spread of knowled beyond the diabetic clinic, and as it spreads th future of the diabetic child will *become steadi* brighter.

HEAT CRAMPS.

THE peculiar condition of cramp in the muscl experienced by men working in high temperature has been *known for many* years. Its chief cause seems to be high temperature associated with high humidity and low air velocity—in other words, interference with loss of body heat. The next most important factor is muscular effort, while a third is the physical condition of the worker. Cramps seldom afflict men working in the open air, however hot it is; *they are usually in the* muscles most vigorously used, and they are most often found in men who have insufficient sleep or food, or too much alcohol, or some intercurrent disease. Moreover, inexperienced men starting on hard work in the heat are especially liable to cramp. Dr. D. M. Glover, who reviews these facts,[1] says that it is the spare, wiry *men* who are most often affected, and that he has never seen a case in an obese person. Twenty-five years ago cramps were believed to be due to the drinking of iced water, and many steel mills supplied tepid water only. Possibly this discouraged the men from drinking large quantities, but otherwise the measure could have had little effect. The theory *that cramp* is due to salt loss is attributed to J. S. Haldane, but salt solution had been used empirically some years before he made the suggestion of giving sodium and potassium chloride in the drinking water. The results proved extremely gratifying, and Glover's recent observations confirm these earlier findings. When the water is salted the men drink less and less often, he finds and yet their thirst is quenched. The trouble has been that salty water is disagreeable to the taste and men often will not drink it consistently. Glove therefore hit on the idea of supplying a salt table to be taken with each drink. Since the worker lose 2 or 3 g. of sodium chloride in an hour of har work, a grs. 16 tablet of sodium chloride was recommended. This is only slightly larger than the ordinar aspirin tablet, and has been found to compensate th salt loss adequately. Glover points out the importance of making everything as simple as possible men will not take trouble, even to save themselve cramp, and they will not go and ask the foreman fo tablets lest they should seem to be complaining o unfit *for* their work. It was therefore arranged tha each drinking tap should have over it a machin delivering one tablet by some simple mechanism-ally a rotating plate. Dr. Glover is unable to duce convincing statistical evidence of the freedom m cramp afforded by this simple means, but he is isfied that the method is well worth introducing any factory where men have to do hard muscular rk at high temperatures.

THE DANGERS OF MOTOR TRAFFIC.

WE have received from the Pedestrians' Association tatement in support of the contention that roads are wing increasingly dangerous to pedestrians owing motor traffic, the view being based upon the first urns under the new Act abolishing speed limit. far as London is concerned the road casualty urns for the metropolitan police area during the st nine months of 1931 show a decrease compared th the corresponding period of 1930, but the sociation considers that conclusions based on the ures for a single area, however large, taken over a atively short period, might be illusory. Despite e metropolitan experience, as shown by figures, e *Association holds that the roads generally throught* the country have become more dangerous for the lking public, and that the flattering message sugsted by the comparison of the first nine months 1930 (1021 deaths) and the first nine months of 31 (963) has an obvious explanation ; there was, e Association points out, a great decrease in the mber of mechanically propelled vehicles in the er year. The figures of the annual census ken by the Automobile Association, and a return the Ministry of Transport are quoted in support this statement, and it is asked pertinently whether detailed analysis and comparison might not reveal relative increase in the casualties. The conclusion the Association, which admits the impossibility of ing precise, is that during 1931 the roads became r the walking public at least 10 per cent. more ngerous, and, while it formulates no conclusions ncerning the attitude of motorists under the new gime, the statement implies that there has been an thinking adoption of the new standard of increased eed. A decrease in motorists' casualties is certainly t consoling to pedestrians ; it suggests that otorists are becoming more careful to avoid accints likely to involve danger to themselves while owing in recklessness towards the pedestrian. he statement issued by the Pedestrians' Association scloses a serious state of affairs, and makes the rminal question in the document reasonable. conditions have become so much worse in normal year of reduced traffic, what will ppen when traffic resumes once more its normal evelopment ?

The Marylebone branch of the British Medical ssociation is holding a meeting to discuss "the ischiefs of motoring" under the chairmanship of ir StClair Thomson at 11, Chandos-street, on an. 27th, when it is to be hoped that the question f the attitude of the drivers of motor-propelled ehicles in regard to pedestrians will be discussed eriously. That the carelessness or confusion of the edestrian may contribute to the number of the atastrophes no one denies, but the assumption is oo often made that the blame lies with the pedesrian. It is an effort of the imagination to describe n inquest connected with a motor catastrophe as n opportunity for a jury to describe a pedestrian s a "jay-walker," and to sympathise with the notorist in his painful regrets, but the description is ot a very violent effort.

THE POSITION OF THE ROYAL INSTITUTE OF PUBLIC HEALTH.

THE Royal Institute of Public Health is compelled to vacate its home in Russell-square, and the acquirement of new premises has become imperative ; the Institute, further, is committed to a scheme of rebuilding inaugurated before the present financial stringency. The site in Russell-square will be utilised by the University of London, where street widening does not absorb it, and the Institute has acquired a freehold site at a cost of £19,256 on the north side of Queen-square, Holborn. The estimated amount required for the erection and equipment of the new building is £30,000, and the Institute has no endowment, and is without funds or income further than its receipts in fees and contributions from public authorities for investigations and analyses. Hence the need for an appeal to the general public who have benefited from the long-standing labours of the Institute, and it may be added here that the principal officials—the Principal, Treasurer, Counsel, Solicitors, Auditor, and Secretaries—act in an honorary capacity. The great claim of the Institute on public support in the crisis is its pioneer activities for the standardisation of health service throughout the country. It started in an unpretentious way with the recognition by a small group of medical practitioners of the doubtful value of certain Diplomas in Public Health granted by universities and medical corporations, inasmuch as they did not form a registrable qualification, and it was decided to form a society with the object of promoting legislation on the subject.

The new Institute was born and its great achievement followed, by the securing of a statutory provision that the possession of the "Diploma in Public Health" (D.P.H.) should be rendered compulsory upon all seeking to hold office as medical officer of health under public authorities. The General Medical Council accordingly undertook the standardisation of the various D.P.H. diplomas ensuring uniformity in the examinations. The Institute proceeded to provide a fully equipped centre for compliance with this curriculum, and in a report to the University of London the G.M.C. Inspectors stated that this was being successfully done. As a matter of fact, since 1886 over 1000 medical practitioners have received training at the Institute, the percentage of success of those presenting themselves for the Diploma in Public Health being as high as 85. Royal recognition was obtained in the Jubilee year of 1897, when Queen Victoria conferred upon the Institute the title of Royal and became its Patron —a position subsequently held by their late Majesties King Edward VII. and Queen Alexandra, and now held by their present Majesties.

The President and Secretaries of the Institute will furnish any information required, and we are asked to state that the cheques of donors to the appeal for funds should be made payable to Lord Meston, Chairman of the Appeal Committee, and crossed "Barclay's Bank, Ltd., Russell-square Branch."

NORTH KENT MUTUAL HOSPITAL ASSOCIATION.—At the recent inaugural meeting of this association at Gravesend it was explained that by means of fixed annual or other periodical payments regular subscribers will obtain institutional treatment without trenching upon the funds of the North Kent Hospital. The income limits of the scheme are as follows : Single man or woman, widow or widower, £200 to £350 per annum ; married man and wife, £250 to £400 ; married man, wife, and children under 16 years of age, £300 to £500. There is a uniform contribution of 6*d.* per week or 1 guinea per annum.

THE RÔLE OF VIRUSES IN THE ÆTIOLOGY OF CANCER.

LATER DEVELOPMENTS OF DR. GYE'S WORK.

By W. CRAMER, D.Sc., M.R.C.S.,
IMPERIAL CANCER RESEARCH FUND.

A RECORD has now appeared of the experimental work carried out by Gye and Purdy during the past six years and devoted to a study of the filtrable tumours of fowls, and in particular to the nature of the infective agent by which these tumours can be transmitted.[1] More than three-quarters of the book are taken up by a detailed account of the experimental work and a discussion of the results. The experimental work is introduced by two preliminary chapters, the contents of which can best be summarised by the headings given by the authors to these chapters. The first heading reads: "The cancer problem as revealed by the facts already established concerning tumours of man and other mammals." The second chapter is entitled: "The cancer problem as revealed by the facts already established concerning filterable tumours of the fowl." In this way the various problems presented by the filtrable fowl tumours are clearly set out. They may be summarised as follows. What is the nature of the infective agent capable of transmitting these fowl tumours in a specific manner? Is it of extrinsic origin—that is to say, is it a virus? Or is it of intrinsic fowl origin—something produced by the tumour cells themselves?

Since now a considerable number of filtrable tumours with widely different histological structure and biological behaviour have been found to occur in the fowl, and since each tumour has its own specific infective agent—or cause—the next question which arises is: How are these causative agents related to each other? Are they all different from each other as the specific nature of their action would seem to imply? Or have they something in common, as one might agree from the fact that they all possess the property of transforming a normal cell into a malignant one? And lastly, there is the question: What is the relation of these fowl tumours to the problem of malignancy in man and in mammals, where filtrable tumours have never been demonstrated?

This is not the first time that these questions have been formulated. They were asked 20 years ago by Rous and his collaborators. They were, however, unable to give an adequate explanation of the relationship of the various filtrable tumours, which they had discovered, to each other, except to postulate for each tumour with a characteristic structure a different specific agent. As regards their relationship to cancer in man and in mammals, they stated bluntly that "the findings of the fowl tumours largely demolish the theoretical basis on which the objections to an extrinsic cause for cancer have been built up." In spite of this statement—or perhaps on account of it—the work of Rous was practically ignored by other students of the cancer problem, and the whole subject was allowed to remain dormant until Gye resumed it. In 1925[2] he published the results of experiments which led him to the conception that the infective agent is not an entity different for each type of neoplasm, but a complex made up of an extrinsic agent—a virus—which may be the same for different types of tumours and which by itself is non-pathogenic—and an accessory chemical factor derived from the malignant cells which i different for different types of tumours and which enables the virus to enter into a normal cell and transform it into a malignant one. Gye then transferred this conception to mammalian tumour and claimed to have demonstrated by his experimental technique the presence of a virus in the malignant tumours of the mouse, of the rat, and of man. A repetition of Gye's work by numerous observers failed to confirm the experimental results on which Gye's conclusion was based, but the activity with which the work on the fowl tumour has since been resumed testifies to the stimulating influence of his work and to the recognition of his contention that the fowl tumours are a true manifestation o malignancy, and that their study may throw ligh on the problem of malignancy in man and in mammals

One method used in Gye's earlier investigation to demonstrate the dual nature of the "infectiv agent"—or "infective complex," as it had bette be called—of the tumour extracts was the inactivatio of the extracts by chloroform, which, acting as a antiseptic, was supposed to kill the virus. Th present work of the authors contains a detaile study of the mode of action of chloroform and certai other antiseptics (phenol and acriflavine) on visib pathogenic organisms such as *B. coli* and the viri of pleuro-pneumonia of cattle. It was found tha a number of hitherto unrecognised factors ma affect the rapidity or completeness with which the pathogenic micro-organisms are killed by antiseptic When a comparison was made with the action these antiseptics on the tumour extracts, the san factors which determined the lethal action on th known pathogenic organisms also affected in like manner the inactivation of the tumour extract It is argued, therefore, from analogy that th inactivation of tumour extracts by antiseptics due to the destruction of a *living* agent. Anoth method of inactivating tumour extracts is by gent heat or by prolonged incubation. A detailed stu of the factors which determine this process lea again by analogy, to the conclusion that inactivati by this process is due to the alteration of a chemic substance. On Gye's reasoning a tumour extract inactivated by an antiseptic should be reactivated by the addition of an extract inactivated by heat. The results obtained in this way are, however, admittedly too irregular to be conclusive. The explanation offered for these irregularities is that the action of antiseptics is not restricted to the living agent, but often leads to changes in other essential constituents of the tumour extract. This line of investigation was therefore abandoned for an entirely new method of analysis of the infective complex by means of immune sera.

For the serological work the authors have employed three different strains of filtrable tumour: the well-known strain Rous No. 1; the Fujinami strain, which is histologically indistinguishable from the Rous No. 1, but which is biologically different in ir as it can be transmitted to a certain breed icks; and thirdly, the Begg endothelioma strain, h has an entirely different histological structure grows more slowly than either of the two other ns. Immune sera were prepared by the repeated tion of extracts of these tumours into ducks, s, and horses. In addition, an immune serum nst normal fowl cells was prepared by repeated tions of fowl embryo into a goat. With these une sera the authors have carried out a variety xperiments which in their variety and ingenuity fascinating to follow. Only a few examples can given here to explain the manner in which the of these sera has enabled the authors to analyse infective complex by allowing these sera to ract with the tumour extract in vitro, and then ing the activity of the mixture by injecting it fresh animals. The normal fowl cell immune m will inactivate the extracts of all the three rent fowl tumour strains. But if the immune m is first treated with normal fowl cells so as bsorb the normal fowl antibody, it has lost its er to inactivate the tumour extracts. Moreover, unabsorbed serum does not inactivate the extracts Fujinami tumour which has grown in a duck. se experiments indicate then that the infective plex of the fowl tumour contains an element fowl origin which is essential for its infective vity.

[1] The Cause of Cancer. By W. E. Gye, M.D., and W. J. Purdy, M.B., Members of the Scientific Staff of the National Institute for Medical Research, London. London: Cassell and Co 30s.

[2] THE LANCET, 1925, ii., 109.

ow the immune sera prepared by injection of articular fowl tumour inactivate tumour extract that particular strain and also of other strains, they do not lose their neutralising power by vious treatment with normal fowl cells. This is lence of the existence in the infective complex of element which is not of fowl origin. This con-ion is confirmed by numerous experiments of ch perhaps the most convincing one is that an nune serum prepared from the tumours of the inami strain grown in fowls will inactivate tumour racts of that strain, even if the extract is made n a tumour grown in a duck. These experiments given in great detail. and the results are recorded grammatically in such a clear manner that they be understood at a glance. The experimental dence presented in this book is impressive, and kes it difficult to evade the conclusion that the ectivity of a tumour extract is due to an "infective nplex," of which one element is of fowl origin, ile another part is of extrinsic origin, that is to say, a virus. The combined action of both these ments is necessary to produce the malignant nsformation of a normal cell. There is also dence that the virus element is the same in ferent tumour strains, but not in all. Of the ee tumour strains used the Rous No. 1 strain d the Begg endothelioma are held to have the ne virus, while a different virus is postulated from e experimental results for the Fujinami strain. is is an unexpected but important conclusion, cause it indicates that tumours histologically ferent have the same virus, while tumours of nilar histological structure may have a different rus. It is the intrinsic fowl element of the infective mplex which is specific for each tumour strain, d which modifies the action of a virus so that the me virus may infect different types of cells and us give rise to different types of tumours.

In the last chapter the authors attack the question the relationship between these fowl tumours id cancer in mammals and in man. Up to this int their views and arguments are presented with a truly scientific objectivity which does not conceal difficulties in interpretation or gloss over apparent contradictions in the experimental results. But in the last chapter the authors have allowed their vision to run away with their objectivity. The cellular theory of cancer is presented as a malevolent influence which has obscured the true vision of the problem and has retarded progress. It is right to point out that the neglect of Rous's important discovery was a mistake, but that is not the fault of the cellular theory but rather of those who look upon a scientific theory as if it represented the ultimate truth which has to be defended like a religious dogma, and do not understand that it is merely a temporary conception which may require modification in the light of further advances in our knowledge. The cellular theory of cancer is based on the fact that it has not been possible so far to demonstrate in mammalian neoplasms an element separable from the cell which could transmit the disease. This is admitted by the authors in the earlier part of their book. The student of cancer is to-day in very much the same position as the physicist. In both cases observations carried out from different points of view have led to two different conceptions which appear to be mutually contradictory. But the physicist does not appear to be worried by this dilemma. As an eminent physicist has put it, he uses the one conception on Mondays, Wednesdays, and Fridays, and the other conception for the rest of the week. In doing so he hopes to reach eventually a position where he can bridge over the gap. In cancer research we have reached a similar position. In fact, the attractiveness of Gye's theory lies in the fact that it presents a possibility of bridging over the gap between a cellular theory and a virus theory. In Gye's own conception the virus by itself is unable to "cause" cancer even in fowls, it requires in addition the presence of a cellular factor. We know from experimental carcinogenesis, and from occupational cancer in man, that a long period of induction, in which visible cellular changes take place, is necessary before cancer can develop. In fowls, too, we know from the age-incidence of spontaneous filtrable tumours that a similar process must occur there. In fact, it appears to be more difficult to produce in fowls cancer experimentally by tar painting than in mice. Even if we admit for the sake of argument that a virus had been demonstrated in the cells of mammalian tumours, we would still have to consider the cellular changes which enable the virus to enter the cell as being responsible for the disease. The cause of occupational cancer would still be the occupation, the cause of experimental tar cancer would still be the chronic irritation produced by tar painting. Cancer would still have to be considered as a local disease at its inception with operative removal as the proper treatment. There is, in fact, no more resemblance between Gye's conception of cancer as a virus disease and the older germ thories of cancer than there is between the conception of the modern chemist on the transformation of certain elements and the attempts of the alchemists to transform lead into gold. In the last pages of their book the authors seem to be engaged more in fanning the embers of an old controversy than to illuminate the cancer problem by the light of their new conception.

The book is one which every student of cancer should read and consider. That is made easy for him, because it is written in a clear, lucid style which stimulates one to follow the authors in their intricate arguments and experiments.

THE DOMICILIARY SERVICE OF A MATERNITY HOSPITAL.

WITH SPECIAL REFERENCE TO PYREXIA AND THE VALUE OF SKILLED NURSING.

By Gladys B. Carter, B.Sc. (Econ.), S.R.N.,
INSPECTOR OF MIDWIVES FOR MANCHESTER; RECENTLY SUPERVISING SISTER, OUT-PATIENT MIDWIFERY, UNIVERSITY COLLEGE HOSPITAL, LONDON.

The nursing records of the maternity district of University College Hospital during 17 months have been analysed for two purposes: (1) to give the material for a critical evaluation of the service of trained nurse-midwives provided by the hospital for women delivered in their homes by medical students; and (2) to see if a study of all cases of pyrexia in the puerperium occurring during that period would throw any light on its causation.

The records relate to 1327 cases of women delivered on the district by medical students and nursed at home, taken consecutively, beginning on Jan. 31st, 1929, and ending on April 29th, 1931. For the survey of pyrexia the next 82 deliveries and puerperia have been added, making 1409 cases in all, and bringing the record to June 30th, 1931. There is a second group of 255 cases delivered and nursed by pupil-midwives during the same period, February, 1929, to April, 1931, of which records have been kept in the same form, and similarly the next 32 cases have been added for the pyrexia survey, making 287 cases up to July 31st, 1931. These additions were made so as to be able to compare the pyrexia rates month by month for two complete years. Only cases which were fully reported and recorded daily in special uniform case-books have been included, with the result that a few cases delivered by medical students have been omitted, either because the nursing records are incomplete or because the nursing was undertaken by an outside maternity association.

In addition to the 1327 cases, 33 cases were seen on the district and brought into hospital either before, during, or after labour—that is, 2·42 per cent. of 1360 cases. This is not quite a correct picture of the percentage admitted to hospital, for it will be remembered that the students attended a few cases besides the 1327.

Up to April 1st, 1930, the student went to the case alone, and was assisted by a handywoman, who might be a relative or friend, or a woman who looked upon herself as quite as good as a midwife and who had "followed the University" for many years, and might possess considerable skill. This procedure obtained for the first 679 cases in the series. After that date a State-registered nurse-midwife started out with the student to each case, and relegated the handywoman to the background as much as she could or dared. The student is in charge of the case and not the nurse. Including the 82 cases added for the pyrexia survey this period refers to 730 cases. The pupil-midwife is always accompanied by a sister or staff midwife until she has had 20 cases, when she may go alone or with a fellow pupil.

EQUIPMENT.

The *student* takes to his case his bag and a sterile drum put ready in a canvas cover. In the bag two kidney dishes, nail-brush, two pair of Spencer Wells forceps, dressing forceps, scissors, cord ligatures, dressings, and catheter are carried sterile. Material for suturing, and a hypodermic syringe for the local injection of 2 per cent. novocain, are also carried sterile. The drum contains a gown, two towels; a small jaconet sheet, mops, and vulval pads.

The chief alterations in the equipment during the period have been the introduction of gauze masks, consisting of eight layers of gauze, about April 1st, 1929; the provision of two sterilised kidney dishes instead of a small douche can, which was never used, and *the substitution of dry sterile gloves for wet ones.*

The *nurse* who goes to the delivery carries, in a small attaché case kept for the purpose, her own mackintosh apron, dry sterile gloves, gauze mask, nail-brush and soap, also a safety razor and bowl. All patients are shaved. She has no apparatus for treatment of any kind, but is equipped to deal with a normal case if by misadventure the baby came in the absence of the student. This has never happened in practice.

Pupil midwives carry a case bag supplemented by an American cloth carrier and no drum. Sterile gowns were done away with early in the period, as it was found that the pupil wanted to dress up early in the case, and then considered herself to be too sterile to attend to the mother's wants. She now wears a carbolised mackintosh apron and freshly laundered sleeves for the upper-arm, and an unstarched handkerchief cap. Dry sterile gloves have been used throughout. Masks were added at the same time as they were given to the students. Clean white stockings are carried for the mother, and a thin large mackintosh to protect the bed.

The *pupils* carry sterilised kidney dishes, a large douche can, and a rectal saline apparatus. A delivery bundle containing a set of mops, pads, towels, ligatures, &c., sufficient for one case, is baked and put into the case bag. This was introduced about a year ago to replace numerous small bags. A small sterile packet for vaginal examination only is used if the case is not coming on.

The *sister-midwife* has a bag of her own containing her own apron, mask, cap and gloves, labour and uterine stimulants. She manages the case entirely, and only calls for medical assistance according to the C.M.B. rules.

The district equipment is completed by the bag and drum kept in readiness for the *obstetric house surgeon.* The drum contains leggings for the mother and a perineal sheet, in addition to the usual contents of the drum carried by the student. In the bag are the midwifery forceps carried sterile, anæsthetic requirements, and a sterilised apparatus for subcutaneous saline. To this has recently been added an intravenous set with sterile gum acacia solution.

Perchloride of mercury in "soloid" form is carried by nurses and students alike. It is used at a strength of 1 in 1000 for mopping the patient and for soaking the hands. *Pure lysol is carried for emergency* cleansing of domestic utensils only. The district sister now takes charge of the entire equipment. The nurses make the necessary stock, and pack the drums. Students sterilise their own instruments and bowls and keep their own bags in order, asking for clean linings, &c., as required.

Throughout the period development has been in the direction not so much of improvement of the equipment carried but of very much greater care in its maintenance and sterilisation. The provision of masks, sterilised kidney dishes, and dry gloves are important changes, but the outstanding feature is the giving up, on a definite date, of the practice of sending a student alone to a case.

NURSING CARE OF THE MOTHER AND BABY.

Before the period under review every woman booking with the hospital knew that she must provide a woman to be with her at her delivery and to nurse her afterwards. During the puerperium the hospital sent a maternity nurse, not always either general-trained or a midwife, to visit the mother and baby to see that all was well, take the temperature, pulse, and respiration, measure the height of the fundus, and inspect the umbilical cord. It was not always possible to visit every day. The student and the obstetric house surgeons also made routine periodic visits. There was no system of regular and uniform reporting of the nursing care.

The new system aimed at providing a fully-trained nurse with the student at each case, and complete nursing of the mother and baby afterwards, the idywoman becoming a home help and doing no atment of any kind. The nurses did not begin go out with the students—except in isolated cases, erally for a complicated delivery requiring the sence of the doctor—until April, 1930. General-ined nurse-midwives were substituted for the ternity nurses from January, 1929, and the 1327 es dealt with were attended by this type of nurse ly. In every case one daily visit at least is paid, cept if Sunday falls on a day after the fifth day of e puerperium, when a visit may be omitted if e case is normal. If there is any illness of mother baby, and always in stitch cases, the nurse does e entire nursing, and in any case of a raised morning mperature or any unsatisfactory condition—e.g., itches in the mother or prematurity in the baby—limited evening visits are paid. Geographically, e district, which is large, falls into three areas, d a proposal was made to give a complete nursing rvice in one area. This was rejected, as it was felt at the available staff should provide skilled nursing here it was most required.

It is not easy to eliminate the handywoman, and in ractice it is found that if a mother engages a satisactory woman who expects to attend to the mother nd bath the baby she is apparently better off—rovided that a skilled nurse goes daily to inspect nd take over if need arise—than the mother who ratefully accepts the full service of the nurse, but whose feeding, house, and children are neglected because there is no competent person to look after them in the absence of the nurse.

The study of the puerperal pyrexia returns tends to show that nursing by the handywoman is an added risk.

From the first a record of the handywoman in attendance at every case has been kept, so that it is accurately known what handywomen have been associated with cases of pyrexia. When a woman books she is asked what provision she has made for her lying-in. She is informed that a nurse will be in attendance at the delivery with the doctor, and is offered the services of the nurse in the puerperium twice a day for the first three days, and once a day for the remaining seven days. If she prefers a handywoman, the result for her will be that the nurse will call and inspect every day, but not in the evenings unless need arises.

There are practically no unbooked cases in the series. Table I. shows the extent of ante-natal care.

TABLE I.—*Extent of Ante-natal Care.*

—	Students' district.		Midwives' district.	
	Cases.	Percentage of total.	Cases.	Percentage of total.
No record of ante-natal examination	13	0·97	—	—
Booking only (in many of these blood for Wassermann test was taken)	71	5·35	11	4·31
One complete examination, obstetric and medical	203	15 22	29	11·37
Variable number of subsequent examinations	1040	78·37	215	84·31

The 84 cases of which there is no record or no complete examination occur, with very few exceptions, in the first six months, as a careful system of follow-up by letter and visiting was built up during that period.

Whether the daily nursing is done by the nurse only or by the handywoman under the supervision of the nurse, the visits are reported in exactly the same way. The nurse carries a printed notebook into which she enters the particulars at the house, and she personally gives her report to the supervising sister or her deputy, who enters it into the ledger with the nurse's name. After her first visit she reports the hour of birth and nature of the delivery, the number of rooms and occupants, state of the house, name and address of the handywoman, her cleanliness or otherwise, and any illness in the house—e.g., impetigo.

The hospital possesses a fund which allows for the giving of ten free dinners to the lying-in mother, also milk. The nurses are expected to find out if the woman is getting sufficient food, and if they consider that the case is one in which a good midday meal is not forthcoming they bring back additional particulars as to the number in family, husband's earnings, and rent. We consider this is a most important factor in the successful recovery of the mother and the establishment of lactation.

Each nurse has her own bag, used for daily visiting only. If she is completely nursing the case she leaves nail-brush, mackintosh apron—Woolworth's 6*d.* aprons are largely used—and, if necessary, bowls at the house, and they are brought back at the end of the puerperium. For inspection visits she carries a nail-brush, apron, and bowls for use as required. Perchloride of mercury, 1 in 1000, is used for mopping and for disinfecting of hands. No equipment, such as thermometer or scissors, may be carried outside the bag.

Stitches are swabbed with normal saline as routine, and every primipara is "jugged" with saline for the first two or three days until œdema and abrasions have disappeared. Bad lacerations are irrigated with a rubber catheter, a boiled-up douche can being left covered up at the house. Any tendency to slough is treated by a change to eusol half strength, and recently by chloramine T, 1 per cent. Cleaning up with hydrogen peroxide is very rarely necessary. Lotio rubra has been used very successfully to small areas not granulating well. No stitch dressings are applied. Liquid paraffin is charted for stitch cases and administered on the same day as delivery. No other aperient is given, and, if required, the bowels are opened about the third day by a simple enema with rectal tube. Normal cases are given two pills "78" (colocynth with ipecacuanha) about the evening of the second day and, if aperients are required during the puerperium, freshly-made senna tea is given. Rubber gloves are carried for use if there is any suspicion of infection about mother or baby, and doubtful cases are attended to in gloves.

The daily particulars are reported under the following heads:—

Mother.—Breasts and nipples; lochia; perineum; fundus; stools; urine; temperature, pulse, and respiration; tongue; sleep; diet; general condition; and treatment.

Baby.—Cradle or mother's bed; clothes, good or bad; umbilicus; diet; stools; urine; vomiting; weight; temperature; skin; eyes; mouth; general condition; and treatment.

Two-minute thermometers were originally used, but recently half-minute ones have been substituted. The nurse puts the thermometer in the mouth while she makes her preparations or looks at the baby, so that it has been in the mouth at least three to five minutes before the temperature is charted. In studying the pyrexia rates it must be remembered that the morning temperature is taken roughly between the hours of 9 A.M. and 12 midday, and the evening temperature between 5.30 P.M. and 6.30 P.M. The baby's temperature is not taken as a routine, except for premature babies, when a rectal thermometer registering down to 85° F. is used, and the reading is looked upon as a check upon the adequacy of feeding and care. The height of the fundus is measured with a ruler.

The nursing care on the pupil midwives' district is exactly similar, and reports are taken in the same way. The pupil does everything for the mother and baby, and for the last year every case has been visited for 14 days. The mother gets up on the tenth day if well, the nurse visiting to bath the baby, and if the mother is a primipara she baths it herself under supervision. The results from the extension of the puerperium are good, lactation is better established in 14 days, and the loss of milk on getting up, which so often occurs because the mother has to grapple with all her household cares unaided, is guarded against. The baby's weight on the fourteenth day is a much better criterion of success or failure or need for modification of the feeding than the tenth day weight. The district sister visits each case several times in the puerperium, and makes a thorough inspection of mother and baby before the case is left.

TABLE II.—*Summary of Cases.*

—	Cases delivered by students	Percentage.	Cases delivered by pupil midwives.	Percentage.

Cracked nipples ..	22	1·65	15	5·88

*N.L. †B.B.A.

Soreness and cracking of nipple occurs generally between the second and fifth days, and is trivial. It is treated with glycerin and boric acid or tinct. benzoin co. Only one case of breast abscess occurred on the students' district and one case of raised temperature, due to inflammation of the breast, which subsided, on the pupils' district. In neither case was there cracking or soreness of the nipples. No routine puerperal treatment of breasts or nipples is carried out. Overfull breasts are treated by support and, rarely, by hot bathing and manual relief. A breast pump is never used. Careful instruction of the mother is relied upon to prevent engorgement. A nipple shield is used if the nipples are poor, but is discarded as soon as possible.

Failure to breast-feed is very rare. In cases o slow establishment of lactation, large babies, or weakl and premature ones, complementary and extra feed of lactose solution 1/8 are given in the first few day Extra milk feeds are never given until late in the puerperium, when it becomes evident that the breas milk is really insufficient. Attendance on the bab is not given up until it is doing well or has bee transferred to the infant welfare clinic. The averag number of visits per patient is 11·18 on the students district and 16·44 on the pupils' district.

SURVEY OF CASES OF PYREXIA.

Records of pyrexia have been kept under thre headings:—

(1) Cases which are notifiable under the Puerperal Pyrex Order, the words "with recurrence within that period being taken to mean a second appearance of 100·4° F. a time *over* 24 hours later than the first appearance in the cases where it has not remained up in the 24-hour peri

(2) Cases which reach 100° F. at any one time duri the puerperium, but do not become notifiable.

(3) Cases which do not reach 100° F., but are 99° F. *over in the morning. The class is a little* indefinite, b includes those cases which run a slightly febrile puerperiu with or without symptoms. It is included so as to see its occurrence has any relationship to the other grou (See Table III.)

TABLE III.—*Pyrexia-rates Before and After Advent Nurses.*

	Students.		Midwives.	
February, 1929, to March, 1930.	Before advent of nurses. 679 cases.		Before advent district siste 118 cases	
	Cases.	Percentage	Cases.	Percenta
(1) Notifiable pyrexia ..	35	5·22	5	4 23
(2) 100°F.	32	4·71	8	6·77

April, 1930, to June, 1931.	After advent of nurses. 730 cases.		After advent dis rict siste 169 cases.	
	Cases.	Percentage.	Cases.	Percenta
(1) Notifiable pyrexia ..	16	2·19	2	1·18
(2) 100° F.	33	4·52	7	4·14
(3) Under 100° F. ..	11	1·5	7	4·14
Torn perineum, 648 cases	40	6·17	2 (on 137 cases).	1·4

A second grouping gives the severity of the pyrexi (*a*) Cases over 102° F.; (*b*) cases 101°–102° (*c*) cases 100°–101° F.; (*d*) cases with temperat of one day only. (See Table IV.)

There are no maternal deaths to consider, eit on the district or on cases brought in during puerperium. All cases are set out monthly to if there is any seasonal variation, but the period too short to draw any conclusions. The follow factors are also considered in their relation pyrexia: (1) Ante-natal care; (2) overcrowding a dirt; (3) character of the labour; (4) the attenda at the labour and during the puerperium.

The figures have been divided up to show incidence of pyrexia before and after the cha in April, 1930, when a general trained nurse-midw began to attend every case delivered by a stude the pupils' district a highly experienced district r began to take out the pupils on Feb. 1st, 1930, ing a similar notable change. Probably before happened—certainly on the students' district— wearing of masks was quite useless, because an asked handywoman was allowed to pore over ipment and patient. The same division has been le of the figures for torn perineums, as they also d to show the effect of more skilled assistance. Tables III. and IV.)

BLE IV.—*Pyrexia-rates Before and After Advent of Nurses (Another Classification).*

February, 1929, to March, 1930.	Before advent of nurses. 679 cases.		Before advent of district sister. 118 cases.	
	Cases.	Percentage.	Cases.	Percentage.
Cases over 102° F. ..	23	3 38	2	1·69
101°–102° F. ..	15	2·2	4	3·38
100°–101° F. ..	17	2·51	7	5 93
With temperature of one day only	14	2·06	—	—

April, 1930, to June, 1931.	After advent of nurses. 730 cases.		After advent of district sister. 169 cases.	
	Cases.	Percentage.	Cases.	Percentage.
Cases over 102° F. ..	12	1 63	1	0·59
101°–102° F. ..	8	1 09	—	—
100°–101° F. ..	15	2·04	4	2·36
With temperature of one day only	15	2·04	5	2·95

A study of Tables III. and IV. shows a drop in the ates of notifiable pyrexia on both districts, and, to certain extent, of all types, but the drop is much more marked in the very mild cases. The greatest drop is also shown to occur in the rates above 102° F. and in the group 101°–102° F. (Table IV.). The one-day group and the 100°–101° F. do not show very much change. It seems to be fair to infer that pyrexia of one day's duration and up to 100° F. is due to fairly constant causes, such as reaction, activity of the breasts, delayed action of the bowels, &c., while the higher rates and the lower rates of longer duration are due to illness of some kind. Cases which run a continued temperature of the 99°–99·8° F. variety always cause anxiety, and sometimes become morbid later on. Full investigation of some of these would probably show uterine infection. From the point of view of nursing precautions they are always treated as possibly infectious. The higher incidence of the lower rates on the midwives' district is possibly due to the larger number of routine evening visits paid.

TABLE V.—*Analysis of Cases of Notifiable Pyrexia.*

—	Students' district. 51 cases.		Midwives' district. 7 cases.	
	1929–1930 Feb.–March. Before nurses.	1930–1931 April–June. After nurses.	1929–1930 Feb.–Jan. Before sister.	1930–1931 Feb.–June. After sister.
(1)	12	5	—	—
(2)	4	1	4	2
(3)	11	2	—	—
(4)	8	8	1	—

(1) Cases brought into hospital, investigated, and uterine sepsis found.
(2) Evidence of uterine sepsis but no investigation made.
(3) Not diagnosed, probably sepsis.
(4) Diagnosed as not septic.

No attempt has been made to classify the non-notifiable pyrexias, but the notifiable cases are divided into four groups, as shown in Table V.

The non-septic cases were assigned to: pyelitis, 5; asthma, 1; small-pox, 1; bronchitis, 2; influenza, 2; pleurisy, 1; rheumatic fever, 1; acute tonsillitis, 1; chest condition, 1; reaction, 1.

Antenatal care.—One case of notifiable pyrexia had had no antenatal care. She had a thrombus. Three cases of the up-to-100° F. type also had had none. On the midwives' district an unmarried primipara was taken as an emergency and ran a mild but notifiable temperature, probably due to sepsis, and one non-notifiable case had been booked only.

Overcrowding.—The housing conditions of the cases were as follows:—

One family to a room ..	345 cases	..	25·99 per cent.
(20·28 per cent. of these were primiparæ.)			
One family to two rooms ..	712 cases	..	53·65 ,,
(11·93 per cent. of these were primiparæ.)			
One family to three rooms ..	167 cases	..	12·5 ,,
,, ,, four ,, ..	58 ,,	..	4·37 ,,
(5·2 per cent. of all cases were living in basements.)			

Six families had seven persons, excluding the new baby, in one room only; 11 families had ten persons in two rooms. In one case there were 12 persons and the baby to two rooms. Of the 17 cases of definite sepsis only one was noted as living under extremely bad conditions.

In this case there were seven persons housed in one filthy basement room. The labour was normal, pyrexia developed on the sixth day, and, on investigation in hospital, uterine sepsis was found, due to a hæmolytic streptococcus. The baby never did well. When the woman again became pregnant she was refused treatment at home, but given a bed in hospital. Labour and the puerperium were normal, and the baby did well.

Many labours were conducted in unsuitable surroundings. Although the mother may not develop sepsis, the baby undoubtedly suffers from spending its first ten days in an overcrowded bed.

On the midwives' district for the present year all cases have been visited antenatally by the sister and pupil, and a careful inquiry made into the suitability of the home and adequacy of the preparations. In many cases great efforts have been made by the mother to clean up the home. Really unsuitable cases have been referred to this hospital or to the municipal hospital.

CHARACTER OF LABOUR IN CASES OF PYREXIA.

In the 51 cases of notifiable pyrexia on the students' district the character of the labour was as follows:—

Normal: 42 (9 primiparæ); B.B.A., 3. Total 45 (88·2 per cent.). *Abnormal:* forceps, 3; twins, 2; abortion, 1. Total 6. Torn perineum in four cases.

The 17 cases of definite sepsis investigated occurred as follows:—

Normal: 13 (3 primiparæ); B.B.A., 1. *Abnormal:* forceps, 2; twins, 1. Total 3. Torn perineum in three cases in multiparæ (forceps, 1; normal labour, 2).

Of these investigated cases only two had had a nurse both at delivery and giving full care in the puerperium. One was a forceps delivery who was found to have a *mild* streptococcal infection of the uterus, and the other a primipara with twins who had a non-hæmolytic streptococcal infection, the temperature not exceeding 101·6° F. Four of the septic cases were nursed by the same handywoman, who also had four non-notifiable pyrexias. No other handywoman had more than two cases, and none near enough together to cause suspicion.

In the seven cases of notifiable pyrexia on the midwives' district there were five cases of normal labour (two primiparæ) and one B.B.A. (Total 6, or 85·7 per cent.) There was one case of twins and one of torn perineum.

THE PROBLEM OF THE CARRIER.

Whenever a case of pyrexia is brought into hospital and the pyrexia is shown to be due to sepsis, every effort is made to track down the cause; the throats of students, obstetric assistants, nurses, and handywomen and husbands are searched for offending organisms, and bags and equipment are disinfected with the utmost care. The suspicion remains that at times a germ is carried, even when entirely different people have handled the cases. One small group of cases is instructive in this connexion.

A multipara was delivered normally on Dec. 1st and developed pyrexia on the 4th; the temperature reached 102·4° F. There were no uterine signs, and the case was not brought in, as it cleared up in a few days and the cause of the pyrexia was, therefore, undiagnosed. A primipara was delivered on Dec. 4th and had a normal puerperium until Dec. 14th, when she became ill; the temperature rose to 104·6° F., and she developed a severe sore-throat. She was admitted and investigated, and found to have a severe hæmolytic streptococcal infection of the throat, but the uterus and vagina were sterile. On Dec. 4th a multipara was delivered normally, and on Dec. 14th her temperature rose to 103·4° F. on the third day and she was admitted. She had a rash and sore-throat; hæmolytic streptococci were found in numbers in the uterus and vagina, and a few in the throat. The pathologist then sent for the first woman and took an intra-uterine swab, finding hæmolytic streptococci. Different students had delivered these women, and different nurses and handywomen had visited them.

No conclusions are drawn, but from the point of view of the person who is responsible for the nursing of cases an undiagnosed pyrexia, especially one with few uterine signs, is a very grave anxiety.

SUMMARY AND CONCLUSIONS.

The maternity district of this hospital was reorganised in 1928 to provide general-trained nurse-midwives to go out with students to deliveries and nurse the mother afterwards. It seems possible to draw the following conclusions from the results so far obtainable:—

1. A skilled nursing service for women delivered in their homes by medical students is of educational value because it teaches how good nursing care during labour, especially prolonged labour, diminishes physical and mental wear and tear in the mother, and during the puerperium helps to restore her to full health and to give the baby a good start in life.

2. The factors which lead to a diminution of the accidents of labour and puerperal sepsis in domiciliary practice are: (*a*) Choice of suitable cases in the antenatal department; (*b*) the displacement of the handywoman; (*c*) the provision and maintenance of adequate equipment, including sterilised dressings, gloves, and masks.

3. Cases of pyrexia not obviously due to non-uterine causes should be brought into hospital and investigated: (*a*) for research, (*b*) to prevent the spread of infection.

I wish to express my gratitude to Prof. F. J. Browne, director of the obstetric unit at this hospital, for allowing me to keep these records and for access to the records of cases brought into hospital, and for many suggestions about this paper.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

THE PROBLEM OF THE SLUMS.

So unexpectedly fruitful have the sweepstak on behalf of hospitals proved that it is hardly surprising that the same method is put forward fo solving other problems. The problem of the Dubl slums is one of long standing, and is no less pressin than it was 20 years ago, notwithstanding th extensive housing schemes that have been carri into effect both by the Dublin corporation and by th Government. At the present time of financi stringency it seems impossible for either of the authorities to undertake any outlay on a large scal at any rate for some years to come. In view of thi some of those who are anxious about the slum proble are casting looks at public sweepstakes as a means raising the requisite funds. A fortnight ago in t Senate of the Irish Free State, a resolution w carried, almost without opposition, asking that t executive council should promote legislation make part of the surplus from sweepstakes promoted under the Public Charitable Hospitals A available for the clearing of insanitary areas a the housing of the working classes. Dr. Gogart who seconded the resolution, suggested that the should be a ten years' extension of the hospit sweepstakes for the purpose of closing up the slu in the country. Sir Edward Coey Bigger, an expe enced sanitary administrator, admitted that knew of no better means of getting the money th through the sweepstakes; and Senator Johnson, w has hitherto opposed the legislation of sweepstak thought that as the country had departed from straight path, it might as well use the money deri from the sweepstakes to prevent disease as to c it. The decision of the Senate has elicited a vigor protest in a leading article in the *Irish Times.* T writer points out that if, as has been done, the ra are to be relieved by the proceeds of sweepstak and housing for the working classes to be provi from the same source, there appears to be no log reason why other public expenditure should not similarly met. The taxes, as well as the ra might be lessened, and the country might fin reach the happy position of being completely paras on the gambling spirit of the world.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

THE HEALTH OF CHILDREN.

Two new publications[1] give important data conc ing the health and sickness of the nation's child and of the use of methods to preserve their he in different parts of the country. The first gives s of the results of the survey made by the med section of the White House conference, results wh it may be remembered, were incomplete when conference met last year. They are not even complete and a further publication is promised h the use of preventive measures by nativity, k, and race, as well as some other analytical erial derived from the survey, will be presented. s doubtless safe to say that no such national ey of child health has ever been made in the in any country, and the administrative methods ented in detail in this publication should prove seful record for those undertaking similar work the future.

---

[1] Health Protection for the Pre-school Child: a nati survey of the use of preventive medical and dental service children under 6. By G. T. Palmer, Dr. P.H., M. Derryb and P. van Ingen [illegible] e White H Conference. Londo [illegible] 1931. Pp. The Health of the [illegible] ickness, phy defects, and morta [illegible] nior statisti U.S. P.H.S. (Public [illegible] Washingt Government Printin [illegible] Pp. 159. 35 cents.

he scope of the surveys analysed by the senior istician of the public health service has been ch more limited, and the question may be asked ether these samples from selected districts represent e random sampling of the 24,000,000 who are imated to be in attendance at educational institu- ns of the United States, or of the 38,000,000 who ong in the same age-groups (5–20). However, in introductory chapter, Dr. Taliaferro Clark says believes that the findings "fairly represent the tent and character of the illness and physical fects that are commonly found in school groups."

Most "health examinations"—i.e., medical aminations—of apparently healthy children, are ven in the first year of life. Those who do not get ch examinations as infants rarely get them before ing to school. Altogether, half the city children six years old have had a health examination, while ly about a third of the rural runabouts have had e same advantage. Customs vary widely from 2 per cent. examined in Berkeley (California) to 1 per cent. in Roanoke (Virginia). Only 11 per cent. f city pre-school children have "dental health xaminations," economic considerations determining ery largely which shall be in the lucky minority. hen the children get to school over three-quarters f them are found to have one or more decayed teeth, hile nearly as many have "one or more defects ther than defective teeth, vision, or hearing." The percentage with decayed teeth gradually decreases during the school years until at college age as many as 40 per cent. are found without any decay at all. Seriously defective vision, on the other hand, becomes gradually more common as age advances. Minor defects of vision decrease, which accords with the observation that the anatomical development of the human eye is not complete until 18 to 20 years of age. The largest proportion of pre-school children immunised against diphtheria is found in Niagara Falls, New York, where half the youngsters are protected. The average for city children under six years is only 14 per cent.—a figure which demonstrates forcibly how much remains to be accomplished in this direction.

In connexion with a study of school absences due to sickness, it is interesting to note that only 18 per cent. of these illnesses received medical attention. One cannot help wondering how such a proportion might be changed under a system of family health insurance. It is true that according to the statistics all cases of pneumonia and diphtheria were attended by a doctor. But are not the statistics perhaps misleading here? These are medical terms requiring medical diagnosis. How many cases of diphtheria, unattended by a physician, may there have been that were reported as "sore-throat"? And only one-fifth of the cases of "tonsillitis and sore-throat" had been visited by a doctor. Colds are, of course, the greatest wasters of school time, being more than twice as important as any other cause, while whooping cough is the disease which keeps its individual victims longest out of school (average, 26 days) followed by scarlet fever (22), pneumonia (21), diphtheria (17), scabies (14·5), and measles (12). Of the total absence from school 57 per cent. is due to sickness and 43 per cent. to "other causes." The proportion of lost time due to sickness is distinctly higher for the younger than for the older children.

STEREOFLUOROSCOPY.

The perfection of a stereofluoroscope for use in hospitals is reported from the California Institute of Technology. The instrument consists of two X ray tubes connected to a single transformer. A fifty-cycle current causes alternate emissions of rays from these two tubes which are spaced at approximately the same distance as the interval between the eyes. The rapidly alternating shadows on the screen are made to give a three-dimensional picture by a device by which each eye shall perceive the shadow thrown by one tube, but not that thrown by the other. The device is a rotating shutter driven by a motor at such a speed that it is synchronised with the alternations in the electric current supplied to the X ray tubes. The instrument is adjustable so that the solid image in front of the screen can be made on exact scale reproduction of the body. Callipers can be introduced into the image to measure the apparent interval between any two parts of the shadow in any plane. The employment of this instrument has been aided by a grant from the Rockefeller Foundation.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

ROCKEFELLER FOUNDATION BUILDING AT SYDNEY.

THE scheme inaugurated in 1928 for a rearrangement of the medical teaching at the University of Sydney has nearly reached completion. It was made possible by two donations—one of £250,000 by Mr. Bosch, to establish Chairs in medicine, surgery, and bacteriology, now held by Profs. Lambie, Dew, and Wright; and the other a gift of £100,000 for the erection of a building to house the new laboratory departments. The plans have now been finished and tenders have been called for the erection of the building. The former medical school will house the departments of anatomy, physiology, and pharmacology. The clinical and allied departments—medicine, surgery, pathology, bacteriology, gynæcology and obstetrics—will be transferred to the new building, which is in close proximity to the Royal Prince Alfred Hospital. Museums and libraries will be included and there will be ample accommodation for individual research workers in the various departments.

STATE LOTTERIES IN NEW SOUTH WALES AND QUEENSLAND.

There is much speculation about the benefits which the New South Wales Hospitals are deriving from the recently instituted State lottery. The State government has not made any figures available about the profits of the lotteries or their destination. It would appear that no additional assistance has been granted to the hospitals, but that the Government has been able to maintain its subsidies, which amount to about £450,000 a year. This may have been difficult without the assistance of the lottery. It is understood, further, that it is the Government's intention to maintain and supplement the general working expenses of the hospitals in the usual way, by subsidy, and then, when additional funds have accumulated, to reduce the large overdrafts which have been built up by some of them. The lotteries are being very rapidly subscribed, two or even three being drawn in a week. At the present rate it has been estimated that the revenue from this source will be nearly £600,000 per annum. The opinion of the hospital secretaries is divided on the question whether the lottery is interfering with voluntary subscriptions. The general opinion appears to be that *if there had been no lottery, there might have been* no subsidy.

The figures are available from the Queensland State lottery known as the Golden Casket; over 300 have been drawn. The first six were conducted under the auspices of the Queensland Patriotic Committee and the proceeds were devoted to movements for the benefit of returned soldiers. The Government took over in March, 1920. The details of the lotteries held under Government control until the end of the last financial year, Nos. 7–298, have been published and it seems that the gross receipts totalled £7,905,467. Of this, £364,881 went to State income-tax; £191,718 to Federal income-tax; postage was £181,804; and working expenses £453,546. Prize money amounted to £4,412,056, 64 per cent. of the gross receipts, and the profit for distribution to hospitals was £2,312,460, which represents about 30 per cent. of the total.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

ARTIFICIAL ABORTION IN COUNTRY PRACTICE.

SHORTLY before his death a few months ago Dr. Alfred Grotjahn, professor of social hygiene at Berlin University, reported a curious incident. He received anonymously the case-book of a doctor who formerly practised in a country town of 25,000 inhabitants, and had kept full notes of all the curettages he had performed. The book was accompanied by a letter asking Prof. Grotjahn to report on the facts described in these notes in the interest of the campaign for the legalisation of artificial abortion. This he did, and it appears from the register that in the one year, 1927, the uterus was emptied not less than 426 times, while the operation was refused in 127 other cases. No woman was operated on whose pregnancy exceeded three and a half months. The majority of them were married; indeed, only 74 were unmarried. In 55 women the operation was performed twice, and in five three times in the same year. Abortion was induced in the doctor's own consulting-room and without anæsthesia, except in a few cases where an anæsthetic was administered by his wife. The operation was done not only when pregnancy was definitely ascertained but also for prophylactic purposes when it was assumed. Cases where it was indicated by disease of the mother were comparatively few. In some cases, however, the father or mother had tuberculosis; in one a mother had given birth to three deaf-mute children, in another to feeble-minded infants. The clientèle included women of every social class, from wealthy proprietors and landowners to minor employees and workmen. Among the unmarried there were seven young women in easy circumstances who lived with their parents and had failed in their use of the contraceptives previously recommended to them.

The register shows clearly how popular artificial abortion has become not only in large cities but also in an ordinary country town. It is regarded as harmless, and has been so in the hands of a m who was obviously an efficient practitioner a according to his notebook, had no death or injury among his patients. He was a co advocate of the legalisation of artificial abor but Prof. Grotjahn saw many objections. Wi who would like to have children, he said, would *compelled by their husbands to have the op* engaged couples would have sexual intercourse more commonly than they now do, and engageme would lead not to marriage but to a prolonged liais He believed, however, that the present law reform, and proposed State assistance for paren with numerous children.

APPLE DIET FOR DIARRHŒA.

Prof. Reyhe says he has had good results wit the treatment of acute gastro-intestinal disorders wit apples.[1] He has tried it on patients suffering from acute gastritis, vomiting, and profuse diarrhœa sometimes with high fever; adults as well as infants The patients must abstain for 12–24 hours from drinking, and during that time eat nothing besid mashed apples. They may eat as many as the like up to 20 a day, in amounts of 100 to 250 g. a each meal. Vomiting and tenesmus soon disappea after a few diarrhœal motions fever decreases, an on the second day the fæces usually become soli In severe chronic diarrhœa—e.g., in tuberculosis sprue—a favourable effect was observed, but it wa only transitory. Reyhe thinks that the tannic aci in the apples is the cause of the benefit, togeth with the reduction of food and especially of flui The method is very simple, and more agreeable the patient than the usual cure by starvation, cast oil, and gruel. After the acute stage a mixed di can be given, but without milk or vegetables for son days.

PHYSICAL AND MENTAL DISABILITY IN GERMANY.

According to a statistical record prepared Dr. Prinzing, of Ulm, the well-known medic statistician, 33,192 blind people have been report in Germany, being 53 per 10,000 of the populatio Besides the totally blind this number includes th who, even with the aid of spectacles, are unable find their way in the street or to see a finger at distance of 1 metre. Of these, 2307 are war victi In 18,911 cases the cause of blindness could ascertained: in 9 per cent. the condition was c genital, in 4·6 per cent. gonococcal infection responsible, and in 15 per cent. glaucoma. Eighty- persons, all foreigners, were blind as a result of sm pox. The number of deaf-mutes was 31,670, being 6 10,000 for men and 5·1 per 10,000 for women. half the cases the condition was said to be congenit when it was acquired it was usually a sequel to sca fever, measles, cerebro-spinal fever, or other infecti Of the deaf-mutes under 20 years of age 88 per ce of those between 20 and 40 years, 82 per cent., those above 40, 44 per cent. were brought up special institutions. A total of 276,467 people w registered as completely infirm, of whom 190, were men, including 82,278 war victims, and 85, women. The causes were congenital defects, infan paralysis, rickets, sequels to diphtheria and tub culosis, injuries, gout and rheumatism, apople and other nervous diseases. The number of sligh infirm was 116,974 men, including 45,007 war victi and 27,190 women. A total of 207,514 were re l as mentally infirm, of whom 6090 were war ıms.

FOREIGN BODIES IN THE BRONCHI.

r. Wessely, writing in the *Archiv fur Klinische ırgie,* describes three interesting cases of foreign es in the bronchi. One was that of a child l 6 years who had inspired a foreign body from a . When impacted it did not produce any ptoms, but when it became loose it caused severe h and its knocking against the vocal cords was ible from some distance. It was removed three ks later by bronchoscopy. The second case was of a child of 10 years; after an operation for -diphtheritic atresia of the larynx a broken ıula was found by radioscopy in the left lower of the lung. After the removal of the cannula operation the infiltration of the lung ceased, and child, who had shown rachitic symptoms, became ıst and developed normally. In the third case apprentice, aged 18, suffered for 18 months from ere attacks of cough, whose cause could not be ertained by internal or laryngeal or radiographic mination. A small shadow was eventually ected on the plate, and under local anæsthesia a wing-pin was removed through the bronchoscope. every case of uncertain troubles of the lung radiophy should be performed to see whether they are to a foreign body.

SOCIAL INSURANCE IN GERMANY.

)f the 64 millions of Germans in 1930, 22 millions ·4 per cent.) were insured against sickness, and his number 16·5 million dependants must be added, o enjoy free treatment. The number of insured inst sickness is thus 60 per cent. of the total ulation. 23·7 millions (35 per cent.) are insured inst accidents, and about the same number against age and invalidity. The insurance against employment includes 16·5 millions (25·8 per cent.). the current year the number of those insured against kness has considerably decreased—probably by nillions—as a result of unemployment.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

FREE CHOICE OF DOCTOR.

THE conflict between the social insurance and edical men in Hungary has reached a new stage th the resolution of the board of directors of the ıtional Medical Association to the effect that the anagement of the Association finally intends to opt the repeated resolutions of its representatives favour of the free choice medical system. ccording to this resolution the old system has to be opped in all sickness insurance institutions and by ın. 1st, 1933, the free choice system must be in tion. The Association was forced into this policy ot only by the pressure of the medical profession, ut also by the attitude of the Social Democratic arty, which in the interest of the public sharply emanded free choice of doctor. The present panel octors are naturally against it, arguing that the resent critical economic conditions make it very ndesirable to disturb them in the well-deserved ositions which ensure them their meagre bread. he management of the Association has appointed a ommittee to study how the panel doctors may be ıdemnified, but even if they do not find a satisfactory solution, they will still have to yield to the interest of the medical profession as a whole.

SEMMELWEIS POSTAGE STAMPS.

At the suggestion of Dr. Tiborius Györi, teacher of medical history in the University of Budapest, the general post office has resolved to issue postage stamps bearing the portrait and name of Semmelweis. The intention of this action is partly to emphasise therewith Semmelweis's Hungarian nationality, which owing to his German-sounding name and to his having published his works in German, is not generally known, and partly to follow foreign example in making popular the names of those who deserve immortality.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

" ECONOMY."

AT the moment retrenchment dominates the mind of everybody, from the top to the bottom, in the various medical departments in India. All of us are engaged in justifying our own posts or in trying to retain as many of our assistants as possible. Most of us are willing to accept any cuts in general expenses, to the extent of almost complete paralysis of our present activities, provided we can keep our trained personnel over the bad years—which we hope will be few. The 10 per cent. cut in our salaries seemed at first to be a disaster, but now we are beginning to feel that nine-tenths of our pay is better than no pay at all.

The research department has, as usual, been the first to feel the axe; two-thirds of the grant of the Indian Research Fund has been cut. The point of view of the non-expert retrenchment committee is obvious: " Medical research is a more or less new idea. Certain medical problems have been solved, much misery has no doubt been obviated, lives may have been spared, which presumably means that money has been saved; but this saving is all rather problematical, especially in times when trade is bad and there is no shortage of labour. In any case there is no harm in giving medical research a holiday for a year or two; so we will give them enough money to carry on the skeleton organisation and the rest must go." What they do not see is that continuity of work is the most important point, and that our handicap in India has not been lack of urgent medical problems, or even of money; it has been the lack of trained personnel. During the last 12 years a useful staff (85 per cent. Indian) has been trained. The cut in the income of the fund will mean the dismissal of part of this staff, and the setting-back of the clock, as far as medical research in India is concerned, for a number of years, even if the grant is again raised to the pre-retrenchment level within a year or two.

The most preposterous suggestion—though one which I am glad to say is unlikely to be accepted by the Government of India—is that the posts of director-general of the Indian Medical Service and of public health commissioner should be abolished. No doubt the proposed abolition of the post of director-general will be hailed with delight by the left wing of the profession in India as a fatal blow to the domination of the Indian Medical Service in India. But no man has shown himself more interested in the aspirations of the independent medical profession in India than General Megaw, and, if there is to be any extensive reconstruction of medical organisations, no one could be better trusted to give impartial advice to the Government of India on this subject. If recruitment for the Indian Medical Service is discontinued—and there are indications that the policy adopted in this country may include such a step—it might be advisable to change his title, but it is in the interests of every member of the medical profession, and indirectly of the population at large, that the Service should have strong representation at the centre.

Bengal has been spared the attentions of a local retrenchment committee, but this does not mean that the strictest economies have not had to be practised. In some instances these economies have necessitated the discontinuance of the use of comparatively expensive specific drugs for which there are no substitutes—a deplorable state of affairs. On the other hand, in Madras, where the necessity for economy is less, we find a very active retrenchment committee cutting the rations and allowances of nurses at an end of the scale and suggesting the abolition of the post of director of public health and his department at the other. One despairs of the intelligence of a body of men who, in the year 1931, can solemnly ask, "what good does the public health department do to anybody ?"

THE INSTITUTE OF HYGIENE.

The building of the Rockefeller All-India Institute of Hygiene in Calcutta[1] is now complete, but the Government of India's promise to finance it on an adequate scale seems to be in danger of being broken. In these hard times, when contracts are being broken right and left, we feel sure the Rockefeller Foundation will forgive this apparent act of bad faith, provided that, when times again become normal, the Government does not attempt to shirk its full obligations. We understand that the grant to the Institute for the next year has been reduced from the originally estimated 3½ lakhs of rupees to 2. It is rumoured that with this reduced sum the director has been asked to open all six sections as previously planned. This of course would be absurd ; suitable men could not be obtained at the salaries he could now offer. The obvious solution is to begin with three, or at most four, sections on the proper scale, and then at a later date to open the remainder. In any case it will be impossible to open on Jan. 1st, 1932, as was hoped.

MEDICINE AND THE LAW.

Abortion Lawful or Unlawful.

THE judicial, or extra-judicial, observations of Mr. Justice McCardie on the law of criminal abortion are intended to focus public attention on what the learned judge sincerely believes to be grave social evils. But where do we stand as the result ? Existing statute law punishes the "unlawful" administering of a noxious thing, or the "unlawful" use of an instrument, with intent to procure miscarriage. The learned judge gives the impression that, in courts where he presides, all abortion will be deemed lawful. If the law is out of touch with public opinion, the law can be changed ; but meanwhile criminal laws which vary from judge to judge create manifest awkwardness. A medical practitioner, let us suppose, is implored by a patient to procure her miscarria in circumstances which, according to accepted p fessional standards, do not justify him in yieldi to her request. Hitherto he could say that what s asks is contrary to law. What is he now to sa Is the Director of Public Prosecutions to suspend proceedings against the amateur abortionists w wreck the health and risk the lives of so many wome Some official action must be taken to clear up t uncertainty. The Home Secretary could make pronouncement by the process of question and ans in the House of Commons when Parliament reasse bles. The Attorney-General might make a statem in the course of a prosecution, and might invite court to concur. The Court of Criminal App might express its views upon the enforcement abrogation of the statute. Or possibly one m Royal Commission might be set up to report recommend. Something must be done.

One hesitates to criticise the habit of judi comment on laws as they ought to be. It is t that the judge's primary duty is to administer laws as they are. But there are classic instan in which the Bench has performed great ser by its comments. The ironic observations of Justice Maule at Warwick Assizes, when he senten to one day's imprisonment a poor man convic of bigamy, had due effect in causing the law to altered. The prisoner's first wife had deserted and gone to live with another man. Maule grav pointed out the various steps, costing probably £1 which the law as it then stood compelled the husb to take in order to obtain a divorce. Mr. Jus McCardie may some day receive the honours due successful reformer. At the moment, however, he added to the medical profession's difficulties.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK EN DEC. 19TH, 1931.

Notifications.—The following cases of infect disease were notified during the week :—Small- 44 (last week 48) ; scarlet fever, 1498 (last week 17 diphtheria, 993 ; enteric fever, 29 ; pneumo 1358 ; puerperal fever, 27 ; puerperal pyrexia, cerebro-spinal fever, 26 ; acute poliomyelitis, encephalitis lethargica, 10 ; dysentery, 13 ; thalmia neonatorum, 87. No case of cholera, pla or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals o London County Council on Dec. 22nd–23rd was as foll Small-pox, 80 under treatment, none under observation (last week 107 and .2 respectively) ; scarlet fever, 1439 ; diphtheria, 1484 ; enteric fever, 9 ; measles, 517 ; whooping-cough, 423 ; puerperal fever, 21 (plus 12 babies) ; encephalitis lethargica, 222 ; poliomyelitis, 3 ; "other diseases," 217. At St. Margaret's Hospital there were 23 babies (plus 8 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there were no deaths from small-pox or enteric fever, 44 (10) from measles, 6 (1) from scarlet fever, 37 (6) from whooping-cough, 24 (3) from diphtheria, 44 (13) from diarrhœa and enteritis under two years, and 132 (27) from influenza. The figures in parentheses are those for London itself.

Nine of the fatal cases of measles were reported from Stoke-on-Trent and 5 from Bolton. Six deaths from whooping-cough occurred in Birmingham and 6 in Liverpool. In Liverpool also there were 3 deaths from diphtheria and 9 from influenza. Four deaths from diarrhœa and enteritis were notified from Birmingham.

The number of stillbirths notified during the week was 244 (corresponding to a rate of 42 per 1000 births), including 38 in London.

PUBLIC HEALTH SERVICES

PUBLIC HEALTH IN THE LOCAL ACTS OF 1931.

HE annual appearance of the Index to the al and Private Acts[1] is a reminder of the arkable local modification of the general utory standard in matters of public health local government. The 112 Local Acts of session (Oct. 28th, 1930, to Oct. 7th, 1931) apy nearly 5000 pages. The Brighton Corporation alone is 400 pages long, but, as it is a consolidating , it is not all fresh law. The large proportion of mon-form clauses in these Local Acts makes it per to repeat again the Select Committee's recomndations that all powers granted to local authorities he last five sessions should now be collected into ew adoptive Public Health Act. This step would ainly save the local councils much time and money. anwhile, to enable medical officers and others to e the latest developments, we set out our annual nmary with special reference to clauses which pear to be novel. We have often commented on legislative innovations of progressively adminised municipalities. A good instance occurs in the r Taunton Act, which locally extends from seven nine years the age-limit under Part I. of the Children t (Infant Life Protection).

INFECTIOUS DISEASES PROVISIONS.

Variations of public health law, noted in previous ars, need no elaborate mention. Familiar clauses out infectious diseases include the power to close nday schools and to exclude children from public ertainments, the municipal supply of antidotes d remedies to medical practitioners with or without arge, measures against milk-borne infection, the wer for a medical officer to enter premises where ere is dangerous infectious disease, and to get ormation from house-occupiers as to ordinary ectious disease cases on their premises, and the ual powers for cleansing and destroying filthy icles. What seems a new power is one in the unton Act, for compulsory disinfection or destrucn (subject to compensation for damage due to gligence) of books, bedding, and clothes used by tients suffering from tuberculosis with discharges. rious groups of infectious diseases provisions apply Gillingham, Tamworth, and Brighton, to measles, rman measles, whooping-cough, chicken-pox, scabies, gworm, and influenza; West Hartlepool adds umps to this list, Romford and Dagenham substitute umps for influenza.

FOOD, BATHS, AND WATER-SUPPLY.

Food-poisoning is notifiable in several areas. e usual ice-cream and potted meat clauses are equent. Suitable larder accommodation has long een a common requirement, backed by the power inspecting food storage. A new power appears the Portsmouth Act (Section 32 (1) (vii)) of ohibiting the placing of gas-meters in pantries, rders, or cupboards where food for human use is ept. Brighton's power to provide municipal cold orage is an interesting enterprise. Portsmouth and outhampton have obtained authority to erect and anage, and to charge fees for the use of, medicated nd other baths, "including baths, the efficient roperties of which are due to agencies other than water." Part IV. of the Surrey County Council Act (Establishments for Massage and Special Treatment) arranges for proper control of places where "radiant heat, light, electric, vapour, or other baths for therapeutic treatment," are available. Reference to this provision was lately made in THE LANCET (1931, ii., 653) in connexion with a London prosecution. There is a saving for medical practitioners' establishments, and for public hospitals and infirmaries, recognised voluntary hospitals, and registered nursing homes. As regards water-supply, we may note the following outstanding features: the power to place water tanks under streets (in the Preston, Doncaster, and Ashton-under-Lyne Acts), the requirements at West Hartlepool as to pumping from, and care of, rainwater tanks and wells in or under houses, the reduced charge for metered supply to approved voluntary hospitals at Brighton, and the compulsory notification at Taunton of the use of a hose-pipe.

PROTECTION OF AMENITIES.

Town-planning and the protection of amenities may nowadays be reckoned close akin to public health. Surrey have created several precedents in 1931. The county has taken powers for acquiring land by agreement either for the purpose of saving a fine view or for controlling the country alongside a river bank or a new road. Section 67 of the Surrey Act, preventing ribbon development along new by-pass roads, is timely. No local authority has any outstanding new power in respect of river pollution or sewerage. Surrey has another new clause to stop the dumping of refuse within the county without consent not only of the county council but also of the local authority in whose area the dump exists. At Tamworth no unauthorised person is to sort over or disturb the contents of dustbins or of refuse tips; the penalty is a fine up to £5. The restriction of advertisements and of offensive trades, the care of trees, and the control of petroleum filling-stations—a point in which some localities are going beyond Section 11 of the Petroleum (Consolidation) Act of 1928—are further efforts to preserve amenities. Nuisance by the ejection of steam or water-gas to the annoyance of the public will be held in check under new powers at Gillingham, Brighton, and Taunton. The often intolerable nuisance of noise is also combated. The Taunton Clause (Section 165), making noise a nuisance within the Public Health Act, may be cited as a precedent. The noise must be "capable of being prevented or mitigated, having due regard to all the circumstances of the case"; and at least three householders must complain. There is a saving for railways exercising statutory powers. Control of noise in the form of crying of newspapers is familiar; control of noise in sales in the market (at Taunton) is new. Several towns insist on silencers for stationary internal combustion engines, and Brighton has a special clause to check noisy speed-boats.

MOVABLE DWELLINGS, CAMPERS AND CAMPING GROUNDS.

In the interests of health and good order, as well as of social and natural amenities, the Surrey Act has some striking novel provisions as to movable dwellings and camping grounds. Local legislation as to dwellers in tents and vans has been increasing in intensity in the past few years in England.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK END

DEC. 19TH, 1931.

Notifications.—The following cases of infectio disease were notified during the week:—Small-po 44 (last week 48); scarlet fever, 1498 (last week 1770 diphtheria, 993; enteric fever, 29; pneumoni 1358; puerperal fever, 27; puerperal pyrexia, 10 cerebro-spinal fever, 26; acute poliomyelitis, encephalitis lethargica, 10; dysentery, 13; op thalmia neonatorum, 87. No case of cholera, plagu or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of t London County Council on Dec. 22nd–23rd was as follow Small-pox, 80 under treatment, none under observat (last week 107 and 2 respectively); scarlet fever, 143 diphtheria, 1484; enteric fever, 9; measles, 517; whoopi [illegible] fever, 21 (plus 12 babies); encep [illegible] poliomyelitis, 3; "other diseases," 2 At St. Margaret's Hospital there were 23 babies (p 8 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, includi London, there were no deaths from small-pox enteric fever, 44 (10) from measles, 6 (1) from scar fever, 37 (6) from whooping-cough, 24 (3) fr diphtheria, 44 (13) from diarrhœa and enteritis un two years, and 132 (27) from influenza. The figu in parentheses are those for London itself.

Nine of the fatal cases of measles were reported fr Stoke-on-Trent and 5 from Bolton. Six deaths fr whooping-cough occurred in Birmingham and 6 in Liv pool. In Liverpool also there were 3 deaths from diphthe and 9 from influenza. Four deaths from diarrhœa a enteritis were notified from Birmingham.

The number of stillbirths notified during the we was 244 (corresponding to a rate of 42 per 10 births), including 38 in London.

iously a place for municipal clinics. The distrust which the midwives formerly viewed the clinics almost entirely disappeared. The maternal th-rate associated with childbirth from 1928 ards was 8·79, 8·33, and 8·57 in Glasgow, to be pared with 6·98, 6·87, and 6·95 in Scotland.

lthough defaulting is much in evidence at the ereal diseases clinics an improvement is noticeable ecially among men. The new cases of congenital hilis dropped from 351 in 1929 to 250 in 1930. umber equal to 14 per cent. of the new cases of te syphilis had less than one month's treatment 27 per cent. had less than three months' treat- nt, and it was estimated that 16 per cent. of the es of acute gonorrhœa were infectious on defaulting n treatment.

bout half of the 4191 new houses were three- med houses of the "intermediate" type. This e has proved the most serviceable for the relief vercrowding under a controlled system of letting. ring the last two years 248 houses have been cated to tuberculous families. Dr. Macgregor ers to the growth of new suburbs within and hout the city, to slum clearance schemes involving 4 houses, to the rehousing of 894 tenants from gerous buildings, and expresses his confidence t the general housing situation is being very sibly relieved by combined municipal and private erprise. The schoolmasters in the eastern area tify to the improvement in every respect ong the rehoused children.

City of Aberdeen.

Dr. H. J. Rae opens his report with an account of ecial investigations carried out at the city laboratory. J. Smith describes the investigation of 221 cases puerperal fever and 25 cases of septic abortion curring in Aberdeen during the last eight years, and inquiry into the source of infection in 18 cases of erperal fever and three cases of septic abortion. Smith shows that hæmolytic streptococci played e predominant part, and that in 21 cases the eptococcus was demonstrated in the throat and se swabs of those in attendance at the confinement. a result, adequate masking is advocated as an dispensable precaution in midwifery practice. pies of Dr. Smith's work have been circulated nongst the practitioners in the city and neigh- uring counties, and suitable outfits are on view r practitioners interested.

During the first six months of the Scottish inquiry to the incidence of tuberculous infection in milk, 5 samples have been examined at the city hospital. 161 samples of raw ungraded milk 8·7 per cent. ere positive; of 46 samples of milk as retailed per cent. were positive; and of 138 samples of steurised milk (excluding Grade A pasteurised) 1 per cent. were positive.

The transfer of the poor-law hospitals to the berdeen Town Council took place in 1927, and as e result of the Local Government Act the coördina- on of the medical services has been completed on regional basis. The medical officer of health of e city is also chief medical officer of the counties Aberdeen and Kincardine. The university rofessors of medicine, surgery, and midwifery have een appointed consultants at the hospitals transferred the municipality, and the hospital and specialist edical services of the city are available for the whole egion, though for the first few years Kincardine- hire comes in as a customer rather than a partner. he arrangement for the common medical services the city and the two counties has proved very atisfactory.

Since 1919 the corporation have built 2714 houses nder housing schemes. Of these, 154 have four ooms with a rental of £32 10*s.*; 1656 have three ooms with a rental ranging from £22 to £28, with a heaper type at £16; whilst 904 have two rooms ith rentals mostly from £13 to £14. It is estimated hat 2500 families are living in sublet houses. No houses were closed in 1930 because alternate accommodation could not be provided.

County of Aberdeen.

Dr. Rae says that it was not possible to continue the immunisation schemes against diphtheria and scarlet fever during 1930. Results as regards scarlet fever have been so unconvincing that this branch of the work will not be continued, but active immunisation of susceptible children against diphtheria will be carried out in populous areas. Dental treatment of school-children is gaining popularity so fast that the staff of dentists will have to be increased. No official arrangements have yet been made for the operative treatment of tonsils and adenoids.

The notifications of non-pulmonary tuberculosis are increasing, probably because of the excellent facilities for treatment provided at Woodend Hospital. In addition to Woodend, the county council have a call on 27 of the 62 beds at the Culter Convalescent Home, which are used as a preventorium for "pretuberculous" children. The county tuberculosis scheme has adequate sanatorium and hospital accommodation, and a waiting-list is practically unknown.

The county has taken full advantage of the provisions of the Housing (Rural Workers) Act, 1926, and since the Act came into operation up to June 30th, 1931, the number of houses reconstructed has totalled 928. Dr. Rae describes this Housing Act as the only one which has assisted in conserving housing in rural areas, and in preventing rural depopulation. Most of the eight districts have realised its importance, but only one of the ten burghs (Huntly) made use of this Act in 1930.

The county council pay 30*s.* per week for patients admitted to the maternity hospital. During 1930, 101 patients were treated in the maternity hospital and 48 in the antenatal annexe at a cost to the county of £133. The nursing services, though fairly comprehensive, are not complete. There are 38 associations and most of them employ Queen's nurses. A grant is paid for the services of these nurses as part-time health visitors, and Dr. Rae would like them to have a training in health visiting before they undertake the work. A number of them are provided with small cars.

The veterinary inspector reports a severe outbreak of cow-pox affecting 90 per cent. of the cows on a large dairy farm. The milkers were also attacked, several being unable to work for some time. One cow suffering from cow-pox was infected on the udder with virulent diphtheria bacilli.

Paisley.

Dr. G. V. T. McMichael shows how necessary it is to provide hospital treatment for pneumonia. During 1930, 80 per cent. of the total notified cases occurred in houses of one and two rooms, which constitute nearly two-thirds of the total houses in the burgh. For the same housing reason, an increase of maternity beds is needed. There were 199 notifications of scarlet fever with six deaths, the highest case fatality for ten years. Diphtheria notifications numbered 111 with a case fatality of 7·2 per cent. Of 40 notifications of ophthalmia neonatorum 20 were proved to be due to the gonococcus. There was no impairment of vision and there has only been one case of blindness from this cause since 1918.

The number of mothers attending the antenatal clinic was 47 more than the previous highest, and in December a postnatal clinic was opened in charge of Dr. Mary Stevenson. The cases of rickets at the child welfare clinics have shown a welcome decrease during the last three years.

The three-year programme includes 400 houses to replace those to be demolished or closed, 510 to abate overcrowding, and 240 to meet the growth of the population. In order to rehouse tenants of uninhabitable houses, 500 two- and three-apartment houses are being built to be let at rentals of 6*s.* 3*d.* and 7*s.* 3*d.* per week, inclusive of rates.

Surrey now gives a lead as to campers and camping. In Surrey "movable dwelling" will include a cart, carriage, truck, tramcar, motor-car, caravan, trailer, or other vehicle used or intended to be used for human habitation, temporary or otherwise. On complaint of the local authority, a court of summary jurisdiction may prohibit movable dwellings in any area to protect local amenities or to save residents or visitors annoyance from noisy, indecent, or other offensive conduct. The local authority may itself provide (and temporarily close) camping grounds, and may make by-laws as to any camping grounds in its district in the interests of proper control, cleanliness, amenities, orderly conduct, or the prevention of annoyance. We may expect such provisions as these to be imitated and elaborated elsewhere in future.

THE VARIETY OF COLLECTIVE ACTIVITIES.

Aerodromes at Doncaster and Taunton, bands and concerts in many cities, education, gas, electricity, and water-supply, libraries and museums, parks and swimming-pools, motor omnibus and tram services, small details like the power to install mechanical washers in wash-houses at Southampton—these features give us a varied picture of local activity. The activity has its own risks. Several localities have taken powers to create a general insurance fund; Gillingham has set up an Education Accident Fund. The fact that this is not a valueless precaution was shown a few weeks ago when a verdict of £1000 damages was awarded to a youth attending a London County Council school for injuries due to the alleged negligence of a teacher.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1930 statistics of Glasgow, the city and county of Aberdeen and Paisley.

Name of district and estimated 1930 population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality in childbirth.
Glasgow .. (1,088,810)	21·4	14·2	1·14	1·32	2·5	2·0	101/34	49	8·6
Aberdeen City (159,006)	20·8	13·1	0·75	1·52	1·7	—	80/31	24	6·1
Aberdeen Co. Extra-burghal (109,826)	20·4	12·1	0·69	1·46	1·3	—	70 } 25*	—	4·8
Burghal.. .. (38,504)	21·7	13·8	0·83	1·53	1·6	—	100

* Death-rate during first 10 days of life. Stillbirths per 100 live births:—Glasgow 4·4, Aberdeen City, 4·9, Aberdeen County 0·7, Paisley 4·8.

Glasgow.

Dr. A. S. M. Macgregor says the outstanding event of the year was on May 15th, when the Local Government Act came into operation, as the result of which the health department has now four main branches—namely, the general public health services; the combined education and child welfare services; the transferred general hospitals and the outdoor medical poor-law services; and the mental services. The transference took place with great ease and smoothness. The original and transferred hospital ' number 6200. The reorganisation of the hospi facilities is under consideration, and its aim is as much elasticity as possible and the adoption of high standards. The distinction between the infectious and the non-infectious sick need not be too rigidly maintained, says Dr. Macgregor. Much excell hospital provision is devoted to the aged and infirm and the chronic sick, who could be accommodated in institutions other than up-to-date hospitals. Further, the improved outdoor medical service with a domiciliary nursing scheme, will tend to sav hospital accommodation. The unification of th services for school-children with the maternity an child welfare work will lead to the general use of join clinics. The systematic attention given to mino ailments is bearing [illegible] nt services the principal [illegible] m dation for acute cases. The number of persons institutions tends to increase, not because there a real increase in mental disorders, but owing to t increasing longevity and the lessening death-rate mental hospitals. Some additional accommodati has been provided in the mental hospitals, and t beds for observation to which mental patients can *admitted without immediate resort to* certificat have been increased by 60 to a total of 250.

Among infectious diseases pneumonia stood prominently during 1930. In the first quarter th was a measles epidemic and during the last quar a high incidence of pneumonia associated with f during December. During this month 129 hours fog in a fortnight were recorded, and on Dec. 2 522 pneumonia beds were occupied in the fe hospitals, exclusive of a large number in the transfer general hospitals. Mild scarlet fever was wid prevalent in the autumn, and the policy of ho treatment was pressed as far as the provisions of Public Health Act permitted. Enteric infecti were mostly of the mild paratyphoid B form efforts to trace the source of infection did not m with success. The death-rate from phthisis was lowest on record; during the last twenty y the death-rate from non-pulmonary tuberculosis fallen more rapidly than that for tuberculosis of lung. The opening of Mearnskirk Hospital (466 b has enabled large numbers of children to be trea under specialist care and by open-air methods.

Much space is devoted to the consideration maternal mortality. Dr. John Walker finds puerperal pyrexia embraces a large number of ailm but connotes sepsis in approximately half the c reported. Advantage was taken of hospital treatm for 93 per cent. of the "fevers" and for 70 per c of the "pyrexias." There is a lower case-fat because more cases are being reported. Dr. Marg Thomas contributes an article on the epidemiol bacteriology, and treatment of puerperal se This study deals with 800 patients treated in Belvedere Hospital, of which 600 were under own treatment between May, 1929, and Janu 1931. About one-quarter of the cases follo abortion or miscarriage. There was a slightly gre tendency to fatal infection in instrumental c Dr. Thomas admits the advantages of gly treatment, but did not find it possible to ado for more than half of the 800 cases, and thinks it be ruled out when the local infection has sprea the adnexa, pelvic cellular tissue, and periton and also when the infection has invaded the b stream. As regards general methods of treatm she concludes that quinine and arsenic and merc preparations and vitamin A are valueless, and in default of an efficient specific serum for the str coccus of puerperal sepsis, the use of a scarla antiserum is the only rational method at pr available. Drs. MacCunn and Wylie describe technique employed at the antenatal clinics and that the primary attendances have increased 1052 in 1923 to 2992 in 1929. Less than half confinements are attended by doctors, so that the yed by the diuresis which is produced as a result treatment. It is well known that some degree of sis plays an important part in many cases of onic pyelitis and cystitis. Prostatic hypertrophy men and pregnancy in women are outstanding mples of lesions which initiate chronic infection the urine, and in many cases of chronic cystitis re is some degree of atony of the bladder. In te pyelitis or cystitis, where the commoner anti- tics are usually contra-indicated, it is an established nical fact that the combination of bland diluent inks with alkaline diuretics results in a flushing t of the urinary tract and amelioration of mptoms together with a lessened degree of infection. vestigation of the action of drugs like benzoates d salicylates, which have been regarded by some useful urinary antiseptics, shows that along with régime of abundant fluids they have a distinct line diuretic action. The same holds good with id phosphate of sodium and with the citrate or etate of potash. It is a moot point therefore hether the efficacy of such reputed antiseptics benzoates and salicylates does not depend in part on the establishment of a free flow of urine. It is worthy of note that hexamine, given in the usual quantity of grs. 40–50 daily in divided doses, is never found in the urine in a concentration sufficient to yield a formaldehyde content stronger than 1 in 5000, which ordinarily will only suffice to inhibit the growth of the common infecting micro-organisms, but will not exert any decided bactericidal action. The available evidence does not justify the assumption that benzoates or salicylates have a definite antiseptic action upon the urine. It does suggest, however, that the known clinical results following the combination of hexamine with ammonium benzoate or phosphate depend upon: (1) the diuresis produced affording mechanical cleansing; (2) the formation of acid urine, unfavourable to bacterial growth and liberating formaldehyde; and (3) the inhibitory effect of the free formaldehyde upon the causal micro-organisms.

CORRESPONDENCE

HE OUT-PATIENT PROBLEM: A SUGGESTED POLICY.

To the Editor of THE LANCET.

SIR,—The want of correspondence between the rge numbers of sick people who go to the out-patient epartments of hospitals and the inadequate means treating them efficiently can be met in one of three ays. First we might increase the staff and organise ttendances so that the accommodation available not overcrowded at any one time. One objection this method in the case of large towns, where he hospitals are usually central and the suburbs re spreading, is that patients have to travel considerable distances. In many hospitals, even with areful organisation, accommodation is insufficient nd there is not space for new buildings. It would e better policy to attract the bulk of patients elsehere by offering them facilities for treatment earer their homes. The out-patient department ould then be of more real use as a centre of conultation or a place for specialised forms of treatment.

Secondly, there is much to be said for the establishment of public clinics. Consider how of late years the reatment of common complaints is being solved or particular sections of the community. School linics have been set up to deal with minor defects nd diseases. These clinics differ from the majority f doctors' surgeries in that the buildings are more uitable for their purpose, there are trained nurses to apply treatment, and a clerical staff to make ppointments, keep records, and deal with correspondence. Adults who have as children experienced these benefits may suggest their extension, and municipal clinics are already being set up for certain classes of adults—e.g., for the antenatal examination of mothers; for patients with rheumatism, tuberculosis, &c.

There is a third method which, in theory at least, would preserve the incentive to effort on the part of individuals—doctors and patients. The majority of people are of independent spirit and willing to pay for their treatment, but the money they have to pay with is limited. If there were a reasonable certainty that they would be quickly cured by treatment they would pay, but if the chance is only small, they are unwilling to risk their money, and tend to put off treatment as long as they can. At length the burden of ill-health may become such that their earning power is lessened and they have then no money to spend. All disease is a social misfortune; and the time to treat it economically is in its beginnings. It is important to get people quite well after injuries, acute illnesses, or in the early stages of diseases which begin insidiously, such as those due to exposure to cold and wet, in order to prevent changes taking place in muscles or joints, or in other organs at a later date.

The writer would like to see the practitioners in a district form themselves into groups each with a house specially built or converted to their use. These medical houses would have consulting-rooms and be equipped not only with means for physical treatment, such as light, heat, baths, massage, but also with a laboratory for routine pathological investigations, and an X ray plant for diagnosis. Practitioners who confined themselves to special branches such as eye work would have their hours there as well as general practitioners. A nursing staff would be engaged to assist, especially in physical treatment, and a clerical staff to keep the books and make appointments. Private surgeries would be superseded by consulting rooms at the common medical house. All classes of patient—poor, insured, and private—would be seen there but not necessarily at the same hours.

The coöperation of groups of practitioners that is here suggested is coöperation in establishing the medical house, equipping it, managing it, and sharing the expense. It does not imply division of responsibility for the treatment of an individual patient. The doctor who is consulted by the patient would be responsible for him to the same extent as he is at present. The effect of setting up such medical houses would be to raise the standard of practice, to make it possible to treat patients more efficiently, and to prevent maladies developing at a distant date—e.g., arthritis as a late result of traumatism or toxic conditions.

A REVIEW OF THE PHARMACOLOGY OF URINARY ANTISEPTICS.

BY JOHN M. JOHNSTON, M.B., F.R.C.S.,
POLLOK LECTURER IN MATERIA MEDICA AND THERAPEUTICS IN THE UNIVERSITY OF GLASGOW.

THE term "urinary antiseptic" is commonly applied to a drug given internally to exert an antiseptic effect on the urine and which itself is excreted by the kidney. It therefore excludes substances which would be held by the renal cells (the hypothetical renal antiseptics) and medicaments injected per urethram, or applied locally by the surgeon. Infection of the urinary passages is common, usually easy to recognise, but often difficult to cure, and so far there is no available drug which can be termed a certain urinary antiseptic yielding constant therapeutic results. A study of the literature shows that the reputation of most urinary antiseptics is founded upon a rather empirical use or upon unsound scientific principles. In reviewing the problems connected with their therapeutic application, certain points must be borne in mind. On the pathological side it is to be remembered that infection may spread to the urinary tract by the blood stream, by the lymphatics, and by direct spread, generally associated with stasis of flow, along the urinary passages themselves. In the initial stages of acute inflammatory infection, the usual urinary antiseptics are contraindicated. In chronic lesions the infecting micro-organisms may be found deep in the epithelial or subepithelial tissues, beyond the reach of antiseptic urine, and in many cases a local immunity is established with little or no subjective symptoms to direct attention to the condition.[1] Moreover, it is useless to expect cleansing of the urinary tract until any source of infection is located and eradicated.

Certain specific organisms such as *B. tuberculosis* and the gonococcus are resistant to many urinary antiseptics. *B. coli* and the pyogenic cocci (usually of mild virulence) are most commonly met with in the chronic lesions under discussion. The coliform group grows freely in acid urine and the cocci more readily in alkaline urine. In infected urine, urea is decomposed with the formation of ammonium carbonate which will eventually render an acid urine alkaline. Once an alkaline medium is obtained, cocci and ammonia-producing micro-organisms multiply rapidly.

THE IDEAL URINARY ANTISEPTIC.

The ideal urinary antiseptic should be rapidly absorbed and excreted, and should have no irritant action on the gastro-intestinal tract, the liver, or the kidney. When taken by the mouth, such a drug may be modified chemically at any part of its course. It meets the selective cellular elements of stomach, bowel, liver, and kidney, and the powerful chemical influences of the blood with its delicate acid-base mechanism. From the renal epithelium it passes highly diluted to the bladder reservoir, the only site where normally the urine remains for any length of time. The antiseptic properties of drugs employed depend upon the form in which they appear and act in the urinary channels. Of the commoner urinary antiseptics, boric acid (as borates), hexamine, and some aniline dyes are excreted unchanged. There is a large group of substances which, although their original chemical composition would indicate potent antiseptic action, are excreted in altered form.
Being potentially toxic irritants they are rendere
inert either by the blood, or (mainly) by the kidney
For instance, the essential oils, including turpenti
when used in safe doses, are excreted as harmles
products, although in such cases as copaiba a portio
may pass unchanged with some resulting antisept
action. Another group includes drugs which a
synthesised or "conjugated" to form non-irritati
and pharmacologically inert bodies. Salicylates an
benzoates are combined with glycocoll to for
salicylurates and hippurates respectively. It h
been shown, however, that the synthetic powers of t
kidney can be overtaxed by sufficient dosage aft
two or three days, when salicylates and benzoat
appear unchanged or unconjugated in the urin
Such unconjugated benzoates exercise a slight inhi
tory action on the growth of *B. coli*, but benzoa
and salicylates are of no demonstrable value
themselves as direct urinary antiseptics. Hex
resorcinol (Caprokol) has a fate similar to that
benzoates, being excreted in conjugated form (
site of detoxication is not yet definitely ascertaine
but some portion appears unchanged and is said
render the urine bactericidal.[3] Clinical experie
over a varied series of cases does not appear to sh
it to be of any exceptional value as compared w
other remedies.

It has been generally recognised that the quest
of urinary antisepsis is closely connected with
reaction of the urine. Rendering the urine
prevents the growth of urea-splitting mi
organisms and tends to be unfavourable to co
The suggestion, however, that urine may be mad
acid as to inhibit the growth of bacteria, such as *B.*
is untenable, as it has been shown that it is imposs
therapeutically to obtain a hydrogen-ion concentra
(pH) of the urine outside the limits of acid norma
although it is comparatively easy to acidify alka
urine.[2] Titratable acidity, estimated in terms
decinormal alkali, is unreliable owing to the d
fluctuation of urinary output in a given case and to
complex buffer action of the urinary salts.
acidity of urine depends mainly upon the degre
preponderance of mono-sodium hydrogen-phosp
(acid) over di-sodium hydrogen-phosphate (alkal
Acid phosphate of sodium, given in doses shor
producing diarrhœa (saline cathartic action) does
increase the true acidity beyond the normal li
owing to salt-buffer action, although it may inc
the titratable acidity in irregular fashion. Ammon
benzoate[2] and ammonium phosphate[4 5] are effi
urinary acidifiers tending to establish the pH
level of 5·5 to 6·0 (7·0 being neutral point).
ammonium radical is converted into urea, and
whole of the acid ion is available for union
the alkaline ions of the blood plasma, thus low
the blood alkalinity, with consequent excretion
proportionate amount of acid sodium phosphat
the kidney to maintain the alkaline equilibrium o
plasma. The corresponding sodium salts do
increase the acid phosphate excretion, as after ab
tion the sodium ions add to the alkaline ions o
blood. Apart from consideration of the reactio
the urine regarded as a culture medium, there is
the important fact that hexamine, one of the
urinary antiseptics, only becomes effective by
gradual liberation of formaldehyde in an acid u

THE PART PLAYED BY DIURESIS.

One aspect of the problem of urinary antise
seems to have escaped due attention—viz., the

ed by the diuresis which is produced as a result reatment. It is well known that some degree of is plays an important part in many cases of onic pyelitis and cystitis. Prostatic hypertrophy men and pregnancy in women are outstanding mples of lesions which initiate chronic infection the urine, and in many cases of chronic cystitis re is some degree of atony of the bladder. In te pyelitis or cystitis, where the commoner antitics are usually contra-indicated, it is an established ical fact that the combination of bland diluent aks with alkaline diuretics results in a flushing of the urinary tract and amelioration of aptoms together with a lessened degree of infection. estigation of the action of drugs like benzoates l salicylates, which have been regarded by some useful urinary antiseptics, shows that along with régime of abundant fluids they have a distinct ine diuretic action. The same holds good with d phosphate of sodium and with the citrate or tate of potash. It is a moot point therefore ether the efficacy of such reputed antiseptics benzoates and salicylates does not depend in part on the establishment of a free flow of urine. It is worthy of note that hexamine, given in the usual quantity of grs. 40–50 daily in divided doses, is never found in the urine in a concentration sufficient to yield a formaldehyde content stronger than 1 in 5000, which ordinarily will only suffice to inhibit the growth of the common infecting micro-organisms, but will not exert any decided bactericidal action. The available evidence does not justify the assumption that benzoates or salicylates have a definite antiseptic action upon the urine. It does suggest, however, that the known clinical results following the combination of hexamine with ammonium benzoate or phosphate depend upon: (1) the diuresis produced affording mechanical cleansing; (2) the formation of acid urine, unfavourable to bacterial growth and liberating formaldehyde; and (3) the inhibitory effect of the free formaldehyde upon the causal micro-organisms.

CORRESPONDENCE

E OUT-PATIENT PROBLEM: A SUGGESTED POLICY.

To the Editor of THE LANCET.

SIR,—The want of correspondence between the ge numbers of sick people who go to the out-patient partments of hospitals and the inadequate means treating them efficiently can be met in one of three ys. First we might increase the staff and organise tendances so that the accommodation available not overcrowded at any one time. One objection this method in the case of large towns, where e hospitals are usually central and the suburbs e spreading, is that patients have to travel conderable distances. In many hospitals, even with reful organisation, accommodation is insufficient d there is not space for new buildings. It would better policy to attract the bulk of patients elsehere by offering them facilities for treatment arer their homes. The out-patient department ould then be of more real use as a centre of conltation or a place for specialised forms of treatment.

Secondly, there is much to be said for the establishent of public clinics. Consider how of late years the eatment of common complaints is being solved r particular sections of the community. School linics have been set up to deal with minor defects nd diseases. These clinics differ from the majority f doctors' surgeries in that the buildings are more uitable for their purpose, there are trained nurses o apply treatment, and a clerical staff to make ppointments, keep records, and deal with correpondence. Adults who have as children experienced hese benefits may suggest their extension, and nunicipal clinics are already being set up for certain lasses of adults—e.g., for the antenatal examination f mothers; for patients with rheumatism, tuberulosis, &c.

There is a third method which, in theory at least, would preserve the incentive to effort on the part f individuals—doctors and patients. The majority f people are of independent spirit and willing to pay for their treatment, but the money they have to pay with is limited. If there were a reasonable certainty that they would be quickly cured by treatment they would pay, but if the chance is only small, they are unwilling to risk their money, and tend to put off treatment as long as they can. At length the burden of ill-health may become such that their earning power is lessened and they have then no money to spend. All disease is a social misfortune; and the time to treat it economically is in its beginnings. It is important to get people quite well after injuries, acute illnesses, or in the early stages of diseases which begin insidiously, such as those due to exposure to cold and wet, in order to prevent changes taking place in muscles or joints, or in other organs at a later date.

The writer would like to see the practitioners in a district form themselves into groups each with a house specially built or converted to their use. These medical houses would have consulting-rooms and be equipped not only with means for physical treatment, such as light, heat, baths, massage, but also with a laboratory for routine pathological investigations, and an X ray plant for diagnosis. Practitioners who confined themselves to special branches such as eye work would have their hours there as well as general practitioners. A nursing staff would be engaged to assist, especially in physical treatment, and a clerical staff to keep the books and make appointments. Private surgeries would be superseded by consulting rooms at the common medical house. All classes of patient—poor, insured, and private—would be seen there but not necessarily at the same hours.

The coöperation of groups of practitioners that is here suggested is coöperation in establishing the medical house, equipping it, managing it, and sharing the expense. It does not imply division of responsibility for the treatment of an individual patient. The doctor who is consulted by the patient would be responsible for him to the same extent as he is at present. The effect of setting up such medical houses would be to raise the standard of practice, to make it possible to treat patients more efficiently, and to prevent maladies developing at a distant date—e.g., arthritis as a late result of traumatism or toxic conditions.

It is not possible for each of us acting alone to be well equipped to supply modern efficient treatment for many of the common maladies, but it is possible by combination to be much better equipped than we are. That the problem is too large to be solved by individual effort alone, is plain from the fact that each practitioner at present is limited in the amount of diagnostic effort he can make and the physical treatment he can give. These would be extended and increased by combination in providing means and facilities. The group could put up the expense where the individual could not. Looked at from the patient's point of view, the expense in treatment could be made tolerable for the individual by the application and extension of existing insurance schemes. Hospital out-patient departments would then become what they should be, places for consultation and for special treatment.

I am, Sir, yours faithfully,

A. R. FRIEL, M.D., F.R.C.S.I.

Devonshire-place, W., Dec. 14th, 1931.

THE OWNERSHIP OF RADIOGRAMS.

To the Editor of THE LANCET.

SIR,—Could any of your readers clear up some points which may be of interest to our profession generally? I, as a patient's private medical adviser, think fit to advise that radiograms shall be taken. The patient agrees, and the radiograms are taken. A report is given to me in consultation with the radiologist, and also contained in a private letter to me in confirmation. So far the matter is clear, I think. Next, I pass the patient on, as a voluntary case, to a mental hospital; a colleague—a local consultant—agrees with my action and advises the patient's relatives accordingly. The patient's next action is to go into the hospital—where our diagnosis is apparently in process of being confirmed—meanwhile the patient is undoubtedly not capable of making a decision where thought is concerned.

The patient's relatives now ask me for the films of the radiograms (there were three), stating that they are their property, as they paid the fee of the radiologist, which is true. But for what did they pay? For the photographs, as in the case of an ordinary portrait? For the doctor's opinion on the films? For both, thus including a trade and a professional matter under one heading?

The actual films have been passed on to the medical superintendent of the mental hospital, and are with the patient's other papers in the proper file. There seems to be some doubt in the minds of those I have consulted as to whose actual property the films are. There may be several claimants: 1. the radiologist, who has sent them to me to support his report. 2. The patient, alternatively her relatives, since they paid the fee in connexion with the radiograms. 3. Patient's medical adviser, as being part of the report addressed in confidence to him. 4. The temporary property of the medical person at a given time in charge of the case; if so, this does not determine the final property owner.

In the case of an ordinary portrait, I understand that the plate belongs to whoever pays for it, and that the reproduction of pictures cannot be undertaken without the authority of that person, actual or implied. In the case of the radiogram, other factors seem to be involved.

I am, Sir, yours faithfully,

H. GEORGE P. CASTELLAIN, M.D. Cantab.

Birmingham, Dec. 22nd, 1931.

SANOCRYSIN IN PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—I was interested to read the papers by Dr. Allon Pask and Dr. Knud Secher and your leading article in THE LANCET of Dec. 19th. Despite the facts that sanocrysin can only be an adjuvant to general treatment, that its sphere of usefulness is limited, that the drug sometimes appears to be ineffective, and that its immediately beneficial effects, when these occur, may not be maintained, I believe its introduction is the most important advance in the treatment of phthisis since the recognition of the value of collapse treatment. Its greatest usefulness perhaps is that it has certainly widened the scope of the applicability of collapse methods. Adverse criticism of sanocrysin is probably based on insufficiently extensive trials, faulty dosage, and unfortunate selection of cases.

My experience of the treatment, dating from a visit to Denmark in 1924 at a time when the original clinical experiments were being carried out, supports the contentions advanced by Dr. Pask both as regards the usefulness of sanocrysin and the efficacy of doses much smaller than those advocated by Dr. Secher. The large doses originally used were followed in almost every case by reactions of all kinds, often very severe and sometimes with serious results to the patient. For some years I employed a system of doses, beginning with 0·1 g. and working up to 1·0 g., completing the course as a rule in under two months. During the past twelve months, however, I have ceased to give one-gramme doses and have also lengthened the period over which a full course of the drug is given. I begin with 0·05 or 0·1 g. and rarely exceed 0·6 g. as the largest dose. The usual interval between doses is a week. The length of the course depends on the patient's tolerance and weight, an uneventful course usually taking from 12 to 16 weeks according to the total amount of the drug administered. This method of administration is thus similar to that used by Dr. Pask.

In my opinion the great advantage of giving these smaller doses over a prolonged period is the diminution in the incidence and in the intensity of the reactions: this, without any apparent lessening of the beneficial effect of the drug on the tuberculous process. In particular, I note that it is now very rare to find even a trace of albumin in the urine, anorexia is less common and when it does occur it is not so marked. Loss of weight is infrequent. In ambulant patients it is as a rule unnecessary to restrict exercise during the course. Ulceration of the mouth is less frequent and less severe. It occurred in slight degree in only three of my first 20 patients treated by this method of smaller dosage. Diarrhœa likewise occurred only in two patients in this group. In one of them it developed early in the course and lasted ten days. Subsequent doses, however, produced no recurrence and the patient had 7·8 g. in all without any further ill-effect. In the second case the treatment had to be abandoned owing to the diarrhœa.

Of the 20 patients referred to, 11 completed their courses of sanocrysin without any febrile reactions whatsoever. Seven had slight rises of temperature on one or two occasions only. One had a sharp rise of temperature to 104° F., but this settled to normal on the fifth day. The remaining patient had a raised temperature, in the region of 99·6° to 100° (mouth) for nearly three weeks after the second dose (0·25 g.). The sputum, however, which had been persistently positive for at least four months me negative and remained so until the patient's rture three months later, though no further crysin was given. In my experience, moreover, le reactions are unnecessary for the effective ing of the drug. I have at times found on ultation signs suggesting a focal reaction without rise of temperature. Finally, with regard to ile reactions I am under the impression that are more common when the distilled water h is used to dissolve the sanocrysin is taken a a flask or rubber-topped bottle containing a mon supply for several injections rather than n a sealed glass ampoule freshly broken for each ction. In the case of the common supply it is sible that bacterial contamination, in particular h saprophytic organisms introduced into the flask ottle with the needle, provides a source of "protein ck," which may account at least in some measure the febrile reactions sometimes seen when such a hnique is followed. Ten of the patients above rred to showed various cutaneous reactions. eight of them these were exceedingly mild—a few ttered papules or pustules about the body and bs. In the other two there was a generalised thema, followed in one case by desquamation. ese more severe complications necessitated an erruption of the treatment, but the course was npleted in both cases without further incident. th patients lost their tubercle bacilli from the itum shortly after the reaction.

In conclusion, my latest experience with sanocrysin pears to support a system of dosage similar to that ed by Dr. Pask.

I am, Sir, yours faithfully,
HILARY ROCHE.

British Sanatorium, Montana, Switzerland,
Dec. 23rd, 1931.

SURGICAL ASPECTS OF BIRTH CONTROL.

To the Editor of THE LANCET.

SIR,—Mr. Frank Cook's letter in your issue of Dec. 19th reveals a certain sympathy towards Mr. Justice McCardie's views on family limitation, so that it is more the pity that he cannot permit his right hand to follow his heart. The fact that we have no absolutely reliable means of preventing conception, or a 100 per cent. effective and safe method of terminating a pregnancy, merely demonstrates the obvious limitations of man's endeavours. But because there is a mortality-rate in even straightforward tonsillectomy or simple appendicectomy, no one disputes the necessity of the operation. What is the mortality-rate of a curettage and how does it compare with the death-rate in childbirth? Of greater significance, how does it compare with that of inexpert and quack methods of terminating pregnancy? The latter risk, however great it is, will continue to be taken by countless women who definitely *do not want the child,* until the law allows them to take their trouble to their medical attendant. With practice comes perfection (forgive the platitude); we can confidently look forward to advances that will follow proportionally to the extent that the question is given practical consideration and application. There is need for birth control research as there is for cancer research. Why should pathological reasons be the only ones that gain the blessings of the law, when any woman can tell of personal and economic reasons of far greater urgency and significance?

The early statistics of laparotomy do not make pretty reading for modern surgeons; yet neither can one regret the failures that brought the advances, nor, to the best of my knowledge, are the surgeons the less respected in memory. Only by constructive and active measures can be brought about the state of perfection to which Mr. Cook refers, whereas by indifference and inactivity a premium is being placed on the dogmas that surround the subject.

I am, Sir, yours faithfully,
S. CHARLES LEWSEN.

College-crescent, N.W., Dec. 22nd, 1931.

THURSDAY.—5 P.M., Dr. J. M. H. MacLeod: Ringworm Infections.

OBITUARY

SIR WILLIAM BENNETT, F.R.C.S.,

CONSULTING SURGEON TO ST. GEORGE'S HOSPITAL.

WE regret to announce the death of Sir William Bennett at his house in London on Christmas Eve. The end was sudden, but Sir William had been in failing health for some time.

William Henry Bennett was a son of Mr. W. F. Bennett, a Wiltshire landowner, and was born in 1852. He was educated privately and entered St. George's Hospital as a medical student in 1870. He held, after qualification as M.R.C.S., the usual resident appointments at the hospital and proceeded to the F.R.C.S. in 1877, being at that time demonstrator of anatomy at the medical school. His early appointments outside his own hospital were as surgeon to the Seamen's Hospital, to the Hospital of St. John and St. Elizabeth, to the Grosvenor Hospital for Women and Children, and to the Belgrave Hospital for Children, so that from the start of his career he was in possession of unusual clinical opportunities.

SIR WILLIAM BENNETT.

[*Photograph by Lafayette*

In 1880, after an interlude of travel with the late Sir Watkin Wynn, he was appointed assistant surgeon to St. George's Hospital, and immediately made a mark as teacher in the school, while in personal work he secured a fortunate start. His progress on the staff was rapid, for in 1887 he became full surgeon, while his private practice soon became a large one. He was a very careful and resourceful operator, and an especially fine orthopædic surgeon, getting particularly satisfactory results in cases of old injuries and stiff joints, while he was an early advocate of the treatment of fractures by modern methods. He wrote mainly upon these subjects and always from a practical point of view, and his papers and publications on injuries and diseases of the knee-joint, on the treatment of recent fractures by massage, and on the management of stiff joints, were widely read; he contributed also the section upon injuries and diseases of the spine to Treves's "System of Surgery." His writing displayed the qualities of his teaching, which was extremely practical, plain, and straightforward. His demonstrations at the out-patient department of the hospital were especially valued by the students, while in his lectures he had the ability to make the path of the learner smooth, never refining on detail, but always keeping important things in front. He was at different times an examiner for the English Conjoint Board in anatomy, for the Royal College of Surgeons of England in anatomy and in surgery for the Fellowship, and for the University of Cambridge.

Bennett's war experiences were limited by the fa of his lameness, but his services to the sick a wounded on their return from the Boer War wer particularly prominent; he was publicly thanked for them by Lord Roberts, and was appointed K.C.V.O. in 1901. At the outbreak of the recent wa he retired from private practice and resigned all h appointments to work for the British Red Cross an Order of St. John, and to serve on the staff of emergency hospitals. He was appointed surgeon King Edward VII. Hospital, and took charge beds in various auxiliary institutions, supervising al several invalid and convalescent homes. For the services he was appointed Knight of Grace of th Order of St. John of Jerusalem and also of the Roy Order of the Redeemer of Greece.

Sir William Bennett's public appointments we very numerous. He was, for many years, H. Inspector of Anatomy; he was surgeon-in-chief St. John's Ambulance Brigade; chairman of Convalescent Homes' Committee, King Edwar Hospital Fund, and of the Lord Wandsworth Ag cultural College; president of the Institute *Hygiene and of the Illuminating Engineers'* Societ and a vice-president of the Seamen's Hospital Soci and of the Invalid Children's Association. discharged the consequent responsibilities scrupulou and *efficiently*.

In private life Sir William was well known as art connoisseur and a collector. He had a fine ta in pictures, and a great knowledge of china, familiarity with the latter being developed by ea experiences in the sale-room. His lameness preclu him from following the usual athletic pursuits of young man, and his original purchases at aucti represented a form of recreation in his spare ti Soon, however, he *developed a real flair*, and the s of his first collection of china made a considera mark in the artistic world, while the prices obtai were a justification of his acumen.

Sir William Bennett was twice married, his f wife being Isabel, daughter of the late Dr. Thor Dickinson, a well-known practitioner in Sloa street, London, and his second, Gladys, daughter the Rev. Allen S. Hartigan, of St. Leonards-on-S He had no children by either marriage.

ADDITIONS TO CLAYTON HOSPITAL, WAKEFIEL The foundation-stone has recently been laid of a ra logical and therapeutic department of this institut The new building is a gift from the West Yorks joint district miners' welfare committee which has m a grant of £12,000. The cost will not exceed £9000; balance will provide the plant for superficial ther leaving a further £3000 to be raised for deep ther equipment.

WINTER IN ENGLAND.—We have received from the joint secretaries of the movement for promoting the resources of British health resorts the announcement of the next step to be taken by the executive committee. The intention is to coördinate efforts to bring to the attention of the public the merits of the British resorts for winter residence, and it is hoped to establish a central bureau at which information can be obtained. A public meeting will be held at the Institute of Hygiene, lent by the Council of that body, on Monday, Jan. 11th, 1932, at 3.30 P.M., when the objects of the committee will be fully stated and explained. A conference has also been arranged to take place at Paignton, Devon, later in the year, with a similar purpose.

st-graduate Course on Nervous Diseases.

At the National Hospital, Queen-square, London, W.C., ost-graduate course on Diseases of the Nervous System l be held from Jan. 25th to March 18th. The general ırse will consist of 32 clinical lectures and demonstrations 3.30 P.M. each weekday, except Wednesday and Saturday, h teaching in the out-patient department on each week- y except Saturday, at 2 P.M., and eight pathological tures and demonstrations on Fridays at noon. Ten tures on the Anatomy and Physiology of the Nervous stem will be arranged on Tuesdays and Thursdays at on if there are enough applicants, and ten clinical demon- ations, chiefly on Methods of Examination of the Nervous stem, will be given on Tuesdays and Thursdays at 5 P.M. ckets entitling the holders to attend the out-patient clinic three months may be had from the secretary of the edical school, to whom all applications should be addressed.

ampstead General and North-West London Hospital.

The second winter session of the Post-graduate School this hospital will open at 4 P.M. on Jan. 6th, when ord Riddell will give an address on the Ethics of Abortion, erilisation, and Birth Control. On succeeding Wednesdays the same hour lectures will be given by Dr. Adolphe brahams (Dietetic Facts, Fads, and Figments), Mr. George augh (Surgical Lesions due to Pneumococcal Infections), r. J. A. Alison Glover (Tonsillitis), Mr. Sidney Boyd emonstration of surgical cases), Dr. W. E. Gye (Cancer), r. W. H. Ogilvie (Common Injuries of the Wrist), Dr. H. ourtney Gage (X Ray Diagnosis of Diseases of Alimentary ract), Mr. A. Sorsby (Ophthalmoscope in Cardiovascular isease), Dr. H. C. Semon (Diseases of the Buccal Mucosa), r H. M. Oddy (Chronic Arthritis), and Mr. H. Lawson hale (Sinusitis and the Common Cold).

University of London.

Dr. O. L. V. de Wesselow, F.R.C.P., has been appointed as from Dec. 1st, 1931, to the university chair of medicine tenable at St. Thomas's Hospital Medical School. Since 1920 he had been chemical pathologist to St. Thomas's Hospital.

Department of Health for Scotland.

Dr. John M. Johnston, at present Pollok lecturer in pharmacology and therapeutics in the University of Glasgow, has been appointed a medical officer in this department.

Pharmaceutical Society of Great Britain.

A meeting of this society will be held at 17, Bloomsbury-square, London, W.C., at 8.30 P.M. on Tuesday, Jan. 12th, when Mr. Walter Deacon will lecture on the Romance of Perfumes.

Royal Empire Society.

Colonel F. E. Fremantle, M.P., will give an address on the Debt of the Empire to British Medical Research at a meeting of this Society at the Hotel Victoria, at 8.30 P.M. on Tuesday, Jan. 19th, with Sir William Willcox in the chair. Application for tickets should be made to the secretary of the Royal Empire Society, Northumberland-avenue, W.C. 2. A dinner will precede the meeting at 7 P.M.

St. Peter's Hospital.

Weekly lectures will be given at St. Peter's Hospital, 10, Henrietta-street, Covent Garden, London, W.C., on Wednesday afternoons at 3 P.M. (in the pathological department). The first lecture, on Jan. 20th, will be by Mr. J. Swift Joly, who will speak on the Examination of Urological Patients.

National Association for the Prevention of Tuberculosis.

The eighteenth annual conference of this association will be held at University College, London, from July 21st to 23rd. The jubilee of the discovery of the tubercle bacillus by Robert Koch will be made a feature of the conference. The address of the association is Tavistock House North, Tavistock-square, W.C. 1.

Presentation to Prof. Blair Bell.

At the annual dinner of the Medical Students' Debating Society of the University of Liverpool, Prof. W. Blair Bell, President of the British College of Obstetricians and Gynæcologists, was presented with his portrait, painted in oils by Mr. J. A. A. Berrie. Prof. Blair Bell, who is retiring from the chair of obstetrics and gynæcology, said that he valued the gift the more because it was the first time that the students had presented a portrait to one of their teachers.

People's League of Health.

At the general meeting of the League held on Dec. 18th, at the headquarters, 12, Stratford-place, London, W., the founder and honorary organiser (Miss Olga Nethersole, R.R.C.) said that it had been in existence for twelve and a half years and during that time eleven travelling scholarships had been awarded. Prof. D. F. Fraser-Harris, medical secretary to the League's bovine tuberculosis investigation, reported that the special committee appointed to deal with the problem had after eighteen months' close study finished its work and would shortly issue a report.

Post-graduate Lectures on Obstetrics.

Lectures will be given at the City of London Maternity Hospital, City-road, E.C., at 5.30 P.M. on Thursdays from Jan. 14th to Feb. 25th. The lecturers will be Dr. J. Abernethy Willett (Lessons Learned from Emergency Admissions), on Jan. 14th; Mr. W. McK. McCullagh (Maternal Mortality), on the 21st; Mr. Arnold Walker (Treatment of Contracted Pelvis), on the 28th; Mr. H. Burt-White (Puerperal Infection), on Feb. 4th; Dr. Sydney Owen (the Newly-born Baby), on the 11th; Dr. H. C. Lucey (the Pathology of Pregnancy), on the 18th; and Mr. R. Christie-Brown (Treatment of Hæmorrhage), on the 25th.

Psychological Problems of Childhood.

The Child Guidance Clinic of the Jewish Health Organisation of Great Britain announces that a short course of lectures on this subject will be given on Tuesdays and Thursdays at 5.30 P.M., beginning on March 1st, at a place to be stated later. It is intended primarily for members of the medical profession and medical students, and will only be held if the number of applicants is not less than 15, but a limited number of others interested in the subject may be admitted if found eligible by the honorary director. In association with the lectures there will be clinical demonstrations. Particulars about the place may be had from the honorary director of the Clinic, Jews' Free School, Bell-lane, Spitalfields, London, E.1.

At the annual dinner of the Medical Students' Debating Society of the University of Liverpool, Prof. W. Blair Bell, President of the British College of Obstetricians and Gynæcologists, was presented with his portrait, painted in oils by Mr. J. A. A. Berrie. Prof. Blair Bell, who is retiring from the chair of obstetrics and gynæcology, said that he valued the gift the more because it was the first time that the students had presented a portrait to one of their teachers.

People's League of Health.

At the general meeting of the League held on Dec. 18th, at the headquarters, 12, Stratford-place, London, W., the founder and honorary organiser (Miss Olga Nethersole, R.R.C.) said that it had been in existence for twelve and a half years and during that time eleven travelling scholarships had been awarded. Prof. D. F. Fraser-Harris, medical secretary to the League's bovine tuberculosis investigation, reported that the special committee appointed to deal with the problem had after eighteen months' close study finished its work and would shortly issue a report.

Post-graduate Lectures on Obstetrics.

Lectures will be given at the City of London Maternity Hospital, City-road, E.C., at 5.30 P.M. on Thursdays from Jan. 14th to Feb. 25th. The lecturers will be Dr. J. Abernethy Willett (Lessons Learned from Emergency Admissions), on Jan. 14th; Mr. W. McK. McCullagh (Maternal Mortality), on the 21st; Mr. Arnold Walker (Treatment of Contracted Pelvis), on the 28th; Mr. H. Burt-White (Puerperal Infection), on Feb. 4th; Dr. Sydney Owen (the Newly-born Baby), on the 11th; Dr. H. C. Lucey (the Pathology of Pregnancy), on the 18th; and Mr. R. Christie-Brown (Treatment of Hæmorrhage), on the 25th.

Psychological Problems of Childhood.

The Child Guidance Clinic of the Jewish Health Organisation of Great Britain announces that a short course of lectures on this subject will be given on Tuesdays and Thursdays at 5.30 P.M., beginning on March 1st, at a place to be stated later. It is intended primarily for members of the medical profession and medical students, and will only be held if the number of applicants is not less than 15, but a limited number of others interested in the subject may be admitted if found eligible by the honorary director. In association with the lectures there will be clinical demonstrations. Particulars about the place may be had from the honorary director of the Clinic, Jews' Free School, Bell-lane, Spitalfields, London, E.1.

OBITUARY

SIR WILLIAM BENNETT, F.R.C.S.,

CONSULTING SURGEON TO ST. GEORGE'S HOSPITAL.

We regret to announce the death of Sir William Bennett at his house in London on Christmas Eve. The end was sudden, but Sir William had been in failing health for some time.

William Henry Bennett was a son of Mr. W. F. Bennett, a Wiltshire landowner, and was born in 1852. He was educated privately and entered St. George's Hospital as a medical student in 1870. He held, after qualification as M.R.C.S., the usual resident appointments at the hospital and proceeded to the F.R.C.S. in 1877, being at that time demonstrator of anatomy at the medical school. His early appointments outside his own hospital were as surgeon to the Seamen's Hospital, to the Hospital of St. John and St. Elizabeth, to the Grosvenor Hospital for Women and Children, and to the Belgrave Hospital for Children, so that from the start of his career he was in possession of unusual clinical opportunities.

SIR WILLIAM BENNETT.

[Photograph by Lafayette

In 1880, after an interlude of travel with the late Sir Watkin Wynn, he was appointed assistant surgeon to St. George's Hospital, and immediately made a mark as teacher in the school, while in personal work he secured a fortunate start. His progress on the staff was rapid, for in 1887 he became full surgeon, while his private practice soon became a large one. He was a very careful and resourceful operator, and an especially fine orthopædic surgeon, getting particularly satisfactory results in cases of old injuries and stiff joints, while he was an early advocate of the treatment of fractures by modern methods. He wrote mainly upon these subjects and always from a practical point of view, and his papers and publications on injuries and diseases of the knee-joint, on the treatment of recent fractures by massage, and on the management of stiff joints, were widely read; he contributed also the section upon injuries and diseases of the spine to Treves's "System of Surgery." His writing displayed the qualities of his teaching, which was extremely practical, plain, and straightforward. His demonstrations at the out-patient department of the hospital were especially valued by the students, while in his lectures he had the ability to make the path of the learner smooth, never refining on detail, but always keeping important things in front. He was at different times an examiner for the English Conjoint Board in anatomy, for the Royal College of Surgeons of England in anatomy and in surgery for the Fellowship, and for the University of Cambridge.

Bennett's war experiences were limited by the of his lameness, but his services to the sick a wounded on their return from the Boer War we particularly prominent; he was publicly thanked for them by Lord Roberts, and was appointed K.C.V.O. in 1901. At the outbreak of the recent he retired from private practice and resigned all his appointments to work for the British Red Cross and Order of St. John, and to serve on the staff of emergency hospitals. He was appointed surgeon to King Edward VII. Hospital, and took charge of beds in various auxiliary institutions, supervising also several invalid and convalescent homes. For the services he was appointed Knight of Grace of the Order of St. John of Jerusalem and also of the Roy Order of the Redeemer of Greece.

Sir William Bennett's public appointments were very numerous. He was, for many years, H.M. Inspector of Anatomy; he was surgeon-in-chief of St. John's Ambulance Brigade; chairman of the Convalescent Homes' Committee, King Edward's Hospital Fund, and of the Lord Wandsworth Agricultural College; president of the Institute of Hygiene and of the Illuminating Engineers' Society, and a vice-president of the Seamen's Hospital Society and of the Invalid Children's Association. He discharged the consequent responsibilities scrupulously and efficiently.

In private life Sir William was well known as an art connoisseur and a collector. He had a fine taste *in pictures, and a great knowledge* of china, his familiarity with the latter being developed by early experiences in the sale-room. His lameness precluded him from following the usual athletic pursuits of the young man, and his original purchases at auctions represented a form of recreation in his spare time Soon, however, he developed a real flair, and the sale of his first collection of china made a considerable mark in the artistic world, while the prices obtained were a justification of his acumen.

Sir William Bennett was twice married, his first wife being Isabel, daughter of the late Dr. Thomas Dickinson, a well-known practitioner in Sloane-street, London, and his second, Gladys, daughter of the Rev. Allen S. Hartigan, of St. Leonards-on-Sea. He had no children by either marriage.

ADDITIONS TO CLAYTON HOSPITAL, WAKEFIELD.—The foundation-stone has recently been laid of a radiological and therapeutic department of this institution The new building is a gift from the West Yorkshir joint district miners' welfare committee which has mad a grant of £12,000. The cost will not exceed £9000; th balance will provide the plant for superficial therapy leaving a further £3000 to be raised for deep therap equipment.

WINTER IN ENGLAND.—We have received from *the joint secretaries of the movement for* promotin the resources of British health resorts the announcemen of the next step to be taken by the executive committee. The intention is to coördinate efforts to brin to the attention of the public the merits of the Britis resorts for winter residence, and it is hoped to establish central bureau at which information can be obtained. public meeting will be held at the Institute of Hygien lent by the Council of that body, on Monday, Jan. 11th 1932, at 3.30 P.M., when the objects of the committee w be fully stated and explained. A conference has also bee arranged to take place at Paignton, Devon, later in th year, with a similar purpose.

e to the conclusion that there is seldom any on to suppose that the cracking of the joints in r parts of the body is in any way different to the king of the finger-joints. Operators may affirm, patients willingly believe, that dislocations or uxations are being reduced and bones pushed k into place, yet I am firmly of the belief that is not so, but that in the majority of instances *joint surfaces have merely been separated.* Here. n, is an obstacle to our reasoning, for why should es be effected by such a simple measure? We apt to think the whole thing humbug, and forget fact that the patient feels better. Suppose, vever, we approach the subject in another way. us grant that patients are cured after certain nipulations, then there must have been something ong before the manipulation. Do not let us qualify t by saying that what was wrong was in the ient's imagination, for very few people desire to ill. All we know is that there was something ong, though we could not detect it clinically or by ray examination.

A Static Disability.

We must remember that an X ray photograph simply the record of a shadow, and we might nsider some conditions that would not be revealed. r instance, with few exceptions, adhesions would t be shown. Any limitation of movement would t be shown, though this might be deduced if the otograph showed actual fracture or dislocation or oss bony lesion. Nor does it indicate whether the echanism by which the joint is actuated is normal, d it is in this connexion that we may find some asonable explanation of the value of what might termed manipulative therapy.

In the simplest joint the movement is confined to exion and extension. There are other joints where ore highly specialised actions—rotation, circum-uction, &c.—come into play, but for our purpose e may simply consider those joints where flexion nd extension are the predominant movements. Thus the terminal interphalangeal articulation we have beautiful example of a hinge-joint, actuated by exor and extensor muscles, but these muscles act nly in one plane. No provision is made for lateral ovement, this, on the contrary, being prevented by teral ligaments. Nor is there any means of move-ent of a rotatory nature; so it is impossible by ny amount of voluntary action to turn the finger ound till the nail faces the same way as the palm f the hand. Conversely, if by violence that joint e put into a state of lateral flexion or rotation, then here is no active muscular effort which will bring the ones back into proper alignment. Moreover, if we ould imagine the joint rotated through 180 degrees, ven without any tearing of the muscles or ligaments, t is doubtful if the muscles would be able to function t all. But far short of such a condition the power f the muscles is beginning to fail. This we can ry for ourselves. Grasp the middle and terminal phalanges of one forefinger firmly in the other hand and forcibly rotate them, when it will be found almost impossible voluntarily to flex the finger at either of the interphalangeal joints.

Muscles, then, have been developed to act most powerfully with their fibres in a certain direction. Any torsion of the muscle or tendon will diminish its power, and we can see from that experiment what little rotation is necessary to put it out of use—so little, in fact, that the joint displacement would not be noticed on an X ray photograph.

Thus far we have considered movements in unusual planes, but if we think of a backward displacement of a finger-joint we have a condition where the opposing sets of flexor and extensor muscles, though still in their usual plane, are unable to function. This may be because there is no mechanism for voluntarily putting traction on the joint—i.e., separating the joint surfaces and thus facilitating the return of the bones to their proper alignment—but is more probably due to another factor, as may be seen in the wrist. Remember that the opposing sets of muscles moving a joint must always act harmoniously together. In flexion the flexors do most of the work, yet the extensors do not play merely a passive part. On the contrary they are actively engaged in paying out slack, so that the movement is steady and controlled, and vice versa, else we would have a flail joint; but there seems to be an optimum position or angle for these opposing muscles to function. Thus the strongest grip is obtained with the wrist dorsiflexed. This gradually weakens till in extreme flexion of the wrist there is scarcely any grip, and we can imagine a position where the muscles are unable to function. Such position, apart from actual dislocation, would probably be a point just beyond extreme flexion or extension.

There would thus appear to be a point which I would liken to the dead centre of the driving wheel of an engine. As we are all aware from playing with toy engines, or working lathe or treadle machines, if the driving wheel has stopped at a certain point no amount of energy expended by the piston will move the wheel, whereas if the wheel be slightly rotated by hand, or if it be levered over the dead centre, the engine again begins to function. But there was never any suggestion that anything had slipped out of place.

Some Conclusions.

I give no detailed descriptions of the manipulations employed. I have simply attempted to clear up certain points wrapt in mystery, and we are now in a position to review the subject as follows.

1. Not unlikely there may be a joint condition which is not shown on an X ray photograph—a state of fixation either in flexion or in extension, or a strain due to or accompanied by a torsion of the muscles, each of them difficult to detect clinically, and all of them accompanied by some pain on pressure, and perhaps with a certain amount of disability or discomfort.

2. During manipulation the joint surfaces are merely separated. The work done is in a way akin to what the engine driver or mechanic does when he levers the driving wheel over the dead centre. Nature is all the time trying to pull the bones into their proper place, and at the moment of separation the opportunity presents itself for things, as they fly back, to rearrange themselves properly. It is not necessary to hear a pop: the pop simply tells us that the joint has been put through its full range of movement.

3. Bone-setters, osteopaths, and chiropractors do not diagnose the joint condition in the terms we have just explained, but speak of dislocations, bones being out, lesions, or subluxations, to signify what they believe to be wrong. It is sometimes argued that patients understand about a bone being out, and that is an expression which they readily accept. That, however, is not quite fair. The joint is, if you like, out of order—it is not functioning properly. When a patient's kidneys or bowels are not functioning properly he is told that these particular organs are out of order, but not that they are out of place.

4. Although they sometimes give a "specific" manipulation, that is, try to make the bones move back along the path through which they have already travelled, they more often trust to luck with a general manipulation. In other words they make a quick diagnosis that there is something wrong with the joint, and simply make the movement of separating the articular surfaces, hoping for the best: and it is surprising how often this succeeds.

5. If anyone is still inclined to think that the popping of joints means the reduction of dislocations, let him try the corresponding joints on the other side of the body. For example, in the treatment of "tennis elbow" a manipulation is often done at the radio-humeral joint, and a distinct click produced. This is often taken to mean, and bone-setters insinuate, that something has been pushed back into place. But if the other elbow—which is presumably sound—be manipulated in the same way, an exactly similar

NOTES, COMMENTS, AND ABSTRACTS

ON BONE-SETTING.*

BY THOMAS MARLIN, M.D. GLASG., D.P.H., D.M.R.E.,

PHYSICIAN IN CHARGE OF THE MASSAGE, LIGHT, AND ELECTRO-THERAPEUTIC DEPARTMENTS AT UNIVERSITY COLLEGE HOSPITAL AND HAMPSTEAD GENERAL HOSPITAL, LONDON.

A STUDY of bone-setting presents peculiar difficulties. It has generally been surrounded by so much quackery, and accompanied by such exaggerated statements, that our profession as a rule has fought shy of getting mixed up with it. Although at times articles have appeared *about* bone-setting, very little help has been given us in the way of useful descriptions of the manipulations. Very few medical men have acquired any skill in the technique employed for different joints, and little or nothing is taught to students, so for our purpose we will assume that the sum of our knowledge is what we have gained by listening to patients who have been treated by bone-setters.

What is the usual story? "I went to so-and-so, and he put back certain bones in my spine which were out of place. I know he put them back because I felt them go, and also heard the noise of them going back into place." Or "I went to another man and he put back five or seven bones in my ankle. I heard them go back with a crack." Or "I went to yet another man and he found a bone 'out' in my elbow or hand and put it back." In each case the patient was impressed with the sound of the bone going back into place.

And what is our attitude? Perhaps we are too apt, in our search after objective signs, to discount much of what our patients tell us. Let us take a concrete example. Some years ago, at a certain London hospital, a woman was sent to me for massage and electrical treatment for pain in her thumb. The pain was situated round the back of the carpo-metacarpal joint, and the patient's impression was that there was something "out." The condition did not respond to the usual treatments, and several X ray photographs were then taken from different angles, corresponding views being taken of the sound hand for comparison. No abnormality was detected in the photographs, and movement was apparently free in all directions, but that did not satisfy the patient, who still insisted that there was a bone out of place. Was this, I wondered, just the type of case which would add to my mortification by drifting to a bone-setter and possibly getting relief? If so, why should not I myself try manipulation?

With one hand I grasped her thumb and applied traction, while the thumb of my other hand applied pressure to the back of her first metacarpal bone at its base. On sharply increasing this pressure I was agreeably surprised to feel the bone move quite distinctly with an audible click, and the patient heaved a sigh of relief saying we had done the trick. Firm hold was kept of her hand till we were ready to take another series of X ray photographs from the same angles as the previous set. I expected to see some shift of the bone registered, but after carefully examining the different sets had to admit that no difference whatever could be detected.

Now several points present themselves for consideration.

1. From that moment the patient was well.
2. Did I bluff the patient? She had maintained that something was out: did my action merely assure that her diagnosis was right, and did that assurance work the cure? Certainly had it been done by some unqualified person I should have been inclined to think it a very good bluff.
3. Perhaps the patient merely imagined she had pain. Against this was the fact that she was a charwoman, anxious to keep at work, and had no time for such nonsense.
4. The gratitude of the patient was genuine. By some means she found out my private address, and sent me a box of cigars as a Christmas present some months afterwards.
5. As no abnormality was detected by carefully examining the X ray photographs, what could have been the condition of the joint prior to the manipulation, and what actually happened during the manipulation?

The fact that the patient felt better merely causes us to shrug our shoulders, and had the manipulation been done by a bone-setter that would only serve to increase our scepticism. But similar cases are thrusting themselves on us with such insistence that sooner or later we are bound to take notice. Few of us ever see any of this so-called bone-setting, and one of our troubles has been to explain the crack which the patient heard. We argue, soundly, that as there was no displacement shown by X ray examination the manipulator did not put any bones back into place, even though he claimed to have done so The only explanation we have seen brought forward is that the sound is due to the breaking down o adhesions.

Now undoubtedly there was a time when fracture were treated by long immobilisation, and adhesion formed which had to be broken down. This i probably where bone-setters scored in previous days but nowadays fractures are treated in quite a differen way, and stiff joints do not so often result. But even should that happen, then the value of breaking down adhesions is quite well understood by medical men and, in fact, this operation is constantly being don by them. It is most often done under a genera anæsthetic, and the technique does not require any elaboration here. If any comment were necessary it would be to advise the operator not to attemp too much at one sitting. Only a small amoun should be done at a time, and immediately afterward massage and movements should be started to maintai what little mobility has been attained. Whe adhesions are broken down there is a characteristi tearing felt by the operator, and there are subsequen pain and effusion according to the amount done The force employed is a steady one, and the strengt necessary may be very considerable, according t the tenacity of the adhesions. It will be observe that this is not strictly a joint manipulation, but i an operation to break down adhesions round th joint, and so allow the bones to move through greater range of movement.

"Springing the Joints."

There is, however, a manipulation which may b described as springing the joints, and probably thi is the manœuvre most commonly employed by bone-setters. This is accomplished by carrying th joint either into extreme flexion or extension, and then with a sudden, sharp, but guarded thrust o jerk, that particular position is slightly exaggerated Or it can be done by either steady or sudden traction Thus we are all familiar with people who are able to crack their fingers by pulling or by forcibly bending them. Also it is possible to make the elbow crack with the joint extended, and the ankle will often give during traction. In these cases there is no question of breaking down adhesions. The force i sudden and not of sufficient strength to do so, and there is seldom any subsequent pain or effusion.

Perhaps the most reasonable assumption is that a vacuum is formed when the joint surfaces are separated, and the sound is due to the sudden rush of gases into the vacuum. This view is furthe supported by the fact that, generally speaking, it is impossible to crack a second time before the lapse o a considerable interval—i.e., apparently not until the gas in the joint has been reabsorbed by the tissues.

Having watched and treated many cases, I have come to the conclusion that there is seldom any reason to suppose that the cracking of the joints in other parts of the body is in any way different to the cracking of the finger-joints. Operators may affirm, and patients willingly believe, that dislocations or subluxations are being reduced and bones pushed back into place, yet I am firmly of the belief that that is not so, but that in the majority of instances the *joint surfaces have merely been separated.* Here, then, is an obstacle to our reasoning, for why should cures be effected by such a simple measure? We are apt to think the whole thing humbug, and forget the fact that the patient feels better. Suppose, however, we approach the subject in another way. Let us grant that patients are cured after certain manipulations, then there must have been something wrong before the manipulation. Do not let us qualify that by saying that what was wrong was in the patient's imagination, for very few people desire to be ill. All we know is that there was something wrong, though we could not detect it clinically or by X ray examination.

---

* From a lecture delivered to the Hampstead and North-West London Post-Graduate Society.

A Static Disability.

We must remember that an X ray photograph is simply the record of a shadow, and we might consider some conditions that would not be revealed. For instance, with few exceptions, adhesions would not be shown. Any limitation of movement would not be shown, though this might be deduced if the photograph showed actual fracture or dislocation or gross bony lesion. Nor does it indicate whether the mechanism by which the joint is actuated is normal, and it is in this connexion that we may find some reasonable explanation of the value of what might be termed manipulative therapy.

In the simplest joint the movement is confined to flexion and extension. There are other joints where more highly specialised actions—rotation, circumduction, &c.—come into play, but for our purpose we may simply consider those joints where flexion and extension are the predominant movements. Thus in the terminal interphalangeal articulation we have a beautiful example of a hinge-joint, actuated by flexor and extensor muscles, but these muscles act only in one plane. No provision is made for lateral [illegible] this, on the contrary, being prevented by [illegible] ments. Nor is there any means of movement of a rotatory nature; so it is impossible by any amount of voluntary action to turn the finger round till the nail faces the same way as the palm of the hand. Conversely, if by violence that joint be put into a state of lateral flexion or rotation, then there is no active muscular effort which will bring the bones back into proper alignment. Moreover, if we could imagine the joint rotated through 180 degrees, even without any tearing of the muscles or ligaments, it is doubtful if the muscles would be able to function at all. But far short of such a condition the power of the muscles is beginning to fail. This we can try for ourselves. Grasp the middle and terminal phalanges of one forefinger firmly in the other hand and forcibly rotate them, when it will be found almost impossible voluntarily to flex the finger at either of the interphalangeal joints.

Muscles, then, have been developed to act most powerfully with their fibres in a certain direction. Any torsion of the muscle or tendon will diminish its power, and we can see from that experiment what little rotation is necessary to put it out of use—so little, in fact, that the joint displacement would not be noticed on an X ray photograph.

Thus far we have considered movements in unusual planes, but if we think of a backward displacement of a finger-joint we have a condition where the opposing sets of flexor and extensor muscles, though still in their usual plane, are unable to function. This may be because there is no mechanism for voluntarily putting traction on the joint—i.e., separating the joint surfaces and thus facilitating the return of the bones to their proper alignment—but is more probably due to another factor, as may be seen in the wrist. Remember that the opposing sets of muscles moving a joint must always act harmoniously together. In flexion the flexors do most of the work, yet the extensors do not play merely a passive part. On the contrary they are actively engaged in paying out slack, so that the movement is steady and controlled, and vice versa, else we would have a flail joint; but there seems to be an optimum position or angle for these opposing muscles to function. Thus the strongest grip is obtained with the wrist dorsiflexed. This gradually weakens till in extreme flexion of the wrist there is scarcely any grip, and we can imagine a position where the muscles are unable to function. Such position, apart from actual dislocation, would probably be a point just beyond extreme flexion or extension.

There would thus appear to be a point which I would liken to the dead centre of the driving wheel of an engine. As we are all aware from playing with toy engines, or working lathe or treadle machines, if the driving wheel has stopped at a certain point no amount of energy expended by the piston will move the wheel, whereas if the wheel be slightly rotated by hand, or if it be levered over the dead centre, the engine again begins to function. But there was never any suggestion that anything had slipped out of place.

Some Conclusions.

I give no detailed descriptions of the manipulations employed. I have simply attempted to clear up certain points wrapt in mystery, and we are now in a position to review the subject as follows.

1. Not unlikely there may be a joint condition which is not shown on an X ray photograph—a state of fixation either in flexion or in extension, or a strain due to or accompanied by a torsion of the muscles, each of them difficult to detect clinically, and all of them accompanied by some pain on pressure, and perhaps with a certain amount of disability or discomfort.

2. During manipulation the joint surfaces are merely separated. The work done is in a way akin to what the engine driver or mechanic does when he levers the driving wheel over the dead centre. Nature is all the time trying to pull the bones into their proper place, and at the moment of separation the opportunity presents itself for things, as they fly back, to rearrange themselves properly. It is not necessary to hear a pop: the pop simply tells us that the joint has been put through its full range of movement.

3. Bone-setters, osteopaths, and chiropractors do not diagnose the joint condition in the terms we have just explained, but speak of dislocations, bones being out, lesions, or subluxations, to signify what they believe to be wrong. It is sometimes argued that patients understand about a bone being out, and that is an expression which they readily accept. That, however, is not quite fair. The joint is, if you like, out of order—it is not functioning properly. When a patient's kidneys or bowels are not functioning properly he is told that these particular organs are out of order, but not that they are out of place.

4. Although they sometimes give a "specific" manipulation, that is, try to make the bones move back along the path through which they have already travelled, they more often trust to luck with a general manipulation. In other words they make a quick diagnosis that there is something wrong with the joint, and simply make the movement of separating the articular surfaces, hoping for the best: and it is surprising how often this succeeds.

5. If anyone is still inclined to think that the popping of joints means the reduction of dislocations, let him try the corresponding joints on the other side of the body. For example, in the treatment of "tennis elbow" a manipulation is often done at the radio-humeral joint, and a distinct click produced. This is often taken to mean, and bone-setters insinuate, that something has been pushed back into place. But if the other elbow—which is presumably sound—be manipulated in the same way, an exactly similar

sound is produced, and no one is likely to argue that the sound elbow had anything " out."

6. Similar sounds can be produced during spinal manipulation. Medical men seldom see any of this work, but I shall never forget the profound impression made on me when I first saw any of it done, and I have never given a first demonstration to any of my colleagues without noting their extreme amazement that such a thing can possibly be done. How wonderful, then, the impression that can be made on patients. They are told in a very confident and emphatic manner that there is a subluxation, a dislocation, or a lesion at a certain part of their spine, from which all their trouble originates. They say to themselves that all this time no doctor has examined their back, yet they come here and this man puts his finger on the very spot. At the back of their minds they conjure up pictures of hopeless cripples with spinal deformity, but this man is very clever and will put them right. Some keep going for years for the " spinal adjustments," partly from admiration of the operator's diagnostic and manipulative skill, and partly through fear of the dire consequences of leaving off the treatment.

7. Bone-setters do not set bones. No one, no matter how ill-informed, would ever dream of going to a bone-setter to have a recent fracture of his arm or thigh attended to, but gladly entrusts this to the badly abused medical practitioner.

RAT EXTERMINATION IN HUNGARY.

THE systematic extermination of rats by means of poison is being attempted by the Budapest Board of Health in view of the immense damage to public health and private property caused by their depredations. The new regulations have been the occasion of a review of the history of the campaign against rats from the earliest times by Dr. E. Nádor, who draws attention to the great variation in the methods of extermination tried. He points out that few have been really successful even for a short period. In Egypt cats were regarded as holy animals because they were observed to kill vast numbers of rats in storehouses containing cereals. But neither cats nor specially trained dogs could exterminate the pest. In the Middle Ages rat charmers abounded. The legend that they were able to entice rats to follow the tunes of a flute or pipe may have been based on their use of poisons, of which the secret was handed down from father to son, and is now lost.

Experiments have been made with different poisons, sometimes with disastrous consequences not only to rats but also to domestic animals, and indirectly to human beings. The use of strychnine, phosphorus, and arsenic has done much damage to animals other than rodents, and weaker poisons have therefore been sought. Barium and thallium were tried but were also found to be dangerous. In quite recent times attempts at rat extermination with thallium caused a man's death in Budapest. The next step in scientific rat extermination was the introduction of bacteria which were meant to produce gastro-intestinal disease in rats, though innocuous to human beings. These bacterial cultures were of little permanent avail, however, because after a certain time the rats became immune to them. They proved efficacious, however, against rural rats, causing widespread epidemics and a significant decrease in numbers. About the end of last century in Greece rural rats appeared in vast numbers in a certain agricultural district, causing great damage. The Greek Government called in Prof Löffler from Germany. He succeeded in preparing a culture which met with great success.

The next phase in rat extermination was the introduction of the use of poison gases. These proved very useful in docks and ships where it is possible to exclude from the field of operation all human beings and domestic animals. More recently attempts had been directed to the discovery of substanc poisonous to rats and innocuous to other animals a to man. *Attention was drawn to the fact* that in t southern parts of Europe a plant, *Scilla maritim* is successfully used against rats though innocuo to man unless the dose is very large. Unfortunate the substance poisonous to rats, is not always prese in the same proportion in the plant. If too litt is taken poisoning does not occur, whereas if is present in large quantity it has an irritating acti upon the stomach and the rat vomits it. It is hope that a substance has now been found in which is com bined the virtues and none of the disadvantag of the poisons hitherto used. It is said to be effic cious in exterminating rats from cities and rur districts if it is used simultaneously over large area

LOCAL GOVERNMENT LAW.

THE principles of local government law in th country, the relations between the central and loc authorities, the powers and finance of local bodie and the control exercised by the law-courts a expounded in an admirable little book by Mr. W. Jennings.[1] As a part of his subject he briefly sketch the progress of public health from the Act of 18 onwards, the appointment of the General Board Health (with the great sanitary reformer Chadwi as one of its commissioners), and the unpopulari which the Board's activities encountered. When t Board, initially created for five years only, w prolonged for another year and was then reforme Chadwick's name was omitted from the commissio " Æsculapius and Chiron," wrote the *Times*, " in t forms of Mr. Chadwick and Dr. Southwood Smit have been deposed, and we prefer to take our chan of cholera and the rest, than to be bullied into health Subsequent changes somewhat relaxed central co trol. It is no doubt true to say that improveme has come about not because of compulsion from t centre but because of a genuine local demand f better services. Founded on lectures delivered in t universities of Leeds and London, Mr. Jennings' boo is to be commended not only to academic studen but also to others who take a practical part in loc government.

ELEMENTS OF PHYSICAL ANTHROPOLOG

AN introduction to physical anthropology recent published is intended for the amateur or beginner who anatomical knowledge is not great, and provides useful elementary survey. Mr. Stibbe deals with t subject zoologically, palæontologically, and ethn logically, in a lucid and interesting manner. A goo though short section on practical anthropologic measurement and examination is included.

HISTORICAL HANDBOOKS IN MEDICAL SCIENCE.

THE third member of the series of small handboo dealing with the history of medical science, produce under the appropriate group-title of " *Clio Medica*, is devoted to anatomy.[3] It is an excellent little boo full of items of information which seem to be uniform reliable. Prof. Corner provides readable sho chapters on histology, embryology, and neurolog and on modern trends, and includes some interestin reproductions of old illustrations. A list of grea importance to the reader whose classical lore ha become threadbare, is given of the old-time autho whose works can be obtained in modern language

ADDRESSES AND ORIGINAL ARTICLES

INJURIES OF TENDONS AND MUSCLES.*

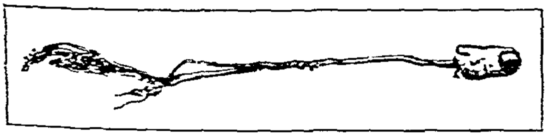
By Harold C. Edwards, M.S. Lond., F.R.C.S. Eng.,
ASSISTANT SURGEON TO KING'S COLLEGE HOSPITAL AND THE EVELINA HOSPITAL.

By virtue of its power of contraction, muscle may of its own accord be responsible for damage to itself or to its tendons of origin and insertion. Under normal conditions the force of contraction is balanced by the tensile strength of the muscle and its attachments, so that the most powerful contraction of the largest muscle may be carried out without fear of injury. If, however, abnormal conditions are present which will reduce the tensile strength or momentarily increase the contractile power, rupture at some point between the origin and insertion of the muscle may occur.

The importance of the contractile power of muscle in relation to injury does not end here however. A contracted muscle is less able to escape injury than a relaxed one, a fact well appreciated by the professional clown, who, by a trick of relaxing his muscles, escapes from the most incredible falls without injury.

A muscle when struck, contracts. Part of any resulting injury is due to the blow and part to the contraction, and it is impossible in most cases to assess the relative importance of the blow and of the contraction in determining the extent of the injury. When a rider jumps into the saddle, the adductors of the thigh contract when the thighs come into contact with the sides of the saddle, but a moment later the thighs are forced apart as the body falls heavily into the saddle, and lastly more violent contraction of the adductors may be made to retain the seat, and rupture of the adductor longus may occur.

FIG. 1.



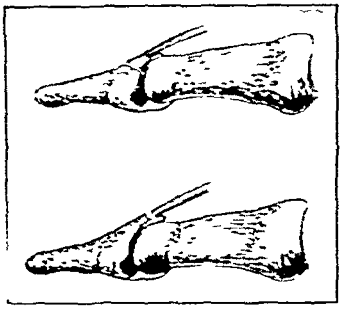
In view of these facts, it is impossible to arrive at a satisfactory classification of muscle and tendon injuries from the ætiological standpoint, and the attempts to do so—many ingenious, all unwieldy and inaccurate—bear evidence to this. As a classification is essential to form a basis for discussion, I shall use the following, which, though admittedly incomplete, has at least the virtue of simplicity. 1. Closed, or subcutaneous injury: (*a*) from external violence (direct and indirect); (*b*) from muscular violence. 2. Injury through open wounds.

Closed or Subcutaneous Injury.

DIRECT VIOLENCE.

A direct blow upon a muscle may produce a temporary inhibition of power without evidence of rupture of muscle-fibres. Such a condition is not uncommon after blows upon the deltoid and quadriceps, and is well known to boxers and Rugby players. The paralysis passes off after a few moments, but may leave the muscle weak for a considerable time. The phenomenon is little understood. It may be due to temporary damage to the nerve-endings within the muscle, as suggested by Ombredanne,[1] but I think it may arise solely from the pain caused by the blow upon the underlying periosteum, for a similar temporary paralysis of the quadriceps may follow a sharp blow upon the patella. Partial ruptures of muscles are of common occurrence from direct blows, and do not call for special comment. Tendons themselves are rarely injured in this way.

FIG. 2.



INDIRECT VIOLENCE.

Both muscles and tendons may be injured from stretching forces, such as in an attempt to reduce a long standing dislocation. Wrenching of a limb caught in machinery may tear the muscles at some distance from the site of the external injury, and examples of rupture of the biceps humeri from this cause are to be found.[2] Avulsion of a tendon due to explosive violence at a point remote from the actual tear in the tendon is another example of rupture from indirect violence. Fig. 1 shows the flexor longus tendon of the index-finger torn away from muscle-fibres—i.e., at the musculo-tendinous junction—as the result of the explosion of a powder flask in the hand.

One of the best examples of rupture of a tendon by indirect violence is that of the insertion of the finger extensor into the base of the distal phalanx, mallet finger. Such an injury may result from a misjudged attempt to catch a hard ball, the impact being taken by the tip of the finger, which is held partially flexed and tense, incurved towards the palm. More trivial injuries, such as tucking in bedclothes, may be a cause in older people, and it is significant that the middle and longest finger is easily the most common one to be affected. Two varieties occur (Fig. 2)—namely, rupture of the tendon, and tearing-off of the prominence at the base of the phalanx into which the tendon is inserted (disinsertion).

There is a choice of treatment between splinting and operation, and good results are to be obtained by either method. The most convenient form of splint is that of Lewin. It is made of aluminium, and holds the distal joint in hyperextension. The splint should be worn for six weeks, and therein lies the disadvantage of the treatment, especially among hospital patients, for they are apt to weary of it, or to remove it at intervals to see how the finger is getting on. For this reason, I prefer operation. An incision is made along the lateral border of the finger extending from the first joint to a point midway between the second joint and the nail bed, and a second joins the distal end of this at right angles.

---

* Based on a paper read before the British Orthopædic Association at Newcastle, on Oct. 31st, and representing a part of the Robert Jones Essay, 1930.

The injury is exposed by turning up the flap so formed, and the proximal end of the tendon is sutured to the periosteum at the base of the phalanx.

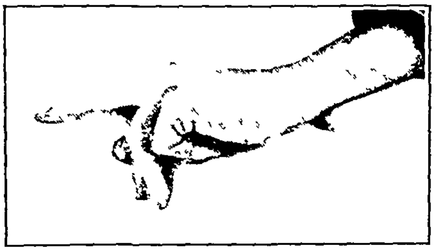
Fig. 3 shows the result obtained in a boy of 12 years. There is no disability. Fig. 4 is of a case of particular interest in that no less than 26 days intervened between the injury and the operation, during which there was no attempt at treatment. Both flexion and extension are slightly limited. The patient is a man of 48 years, who ruptured the tendon tucking in bedclothes. The deformity of the nail which follows operation is due to disturbance of the nail bed, and disappears in two to three months.

The baseball finger of American authors[3] is a similar injury, but in this case it is the extensor slip to the middle phalanx which breaks. The deformity is characteristic, with the proximal joint held in slight flexion, and the distal extended, but not hyper-extended. This injury may cause snapping or trigger finger. A woman, aged 50, felt a snapping sensation in the ring-finger of the left hand when carrying a coal-scuttle, and the finger has been weak since. Four years later I saw her on some other account. The ring-finger is held in the characteristic position described. It can be flexed up into the palm, but after remaining in flexion for some time after the other fingers are extended again, shoots involuntarily into extension with a snap. The condition is probably due to dislocation forwards of the two intact slips of the extensor, so that the head of the first phalanx is imprisoned between them, and on contraction of the extensor with the finger flexed the patient is unable to straighten it, but grips the head of the phalanx more tightly. The finger straightens out with a snap when both extensors and flexors are relaxed together.

MUSCULAR VIOLENCE.

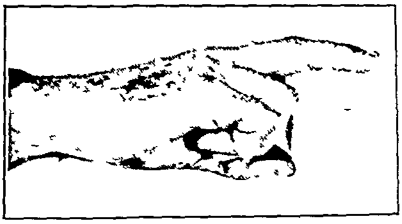
Strain of muscle is a common result of muscular violence. We may use the term to denote a painful minor injury to a muscle in which there is no evidence of gross rupture. The exact pathology of the condition is unknown, for there is no opportunity for detailed pathological investigation. In perhaps the majority of cases of strain of muscle, however, there is clinical evidence that the condition is due to rupture of a few fibres within the muscle substance. The physical signs are a localised area of deep tenderness and a temporary loss of power, either partial or complete. The tear in the muscle may be limited to intramuscular connective tissue, a small patch of hæmorrhage, or of œdema resulting.

FIG. 3.



Before accepting such a hypothesis in explanation of every case, attention is drawn to the condition of what might be called subacute strain of muscle that may follow violent exercise, especially if the muscle be unaccustomed to such exercise. After the first Rugby match of the season the leg muscles may become stiff and painful on movement. There may be generalised or localised tenderness to pressure over the muscle. The condition is, in fact, clinically identical with the acute strain of muscle, except that it is more widespread. It is probably due to an accumulation of an exudate between the muscle fibres resulting from delayed absorption of the products of excessive metabolism. I lean to the view, however, that the exudate is of traumatic origin. The attachments of the muscle-fibres to the fibrous tissue within the muscle is subjected to a long series of "insults" by the frequent and violent contraction of muscles unprepared by training for the exercise. That the condition is ultimately due to an exudate, whatever be its origin, is shown by the nature of the most effective treatment. If left alone the soreness wears off slowly. Heat and massage and exercises readily improve the condition by aiding absorption of the exudate. Exercises are of special importance, for the stiffness can often be worn off by a violent repetition of the exercises which gave rise to it originally, once the agony of the first ten minutes or so is over. A parallel condition of the tendons, clinically if not pathologically, is tenosynovitis resulting from excessive use.

FIG. 4.



The effect of an acute strain of muscle upon the rest of the muscle is of paramount importance from the standpoint of treatment. The refusal of the strained muscle to contract is due either to a temporary paralysis of the muscle, or, more probably, to reflex inhibition, as contraction is now painful. If left alone the muscle may progressively lose power, and the strain is likely to become chronic or recurrent. Furthermore, movement may be limited by adhesions or localised contraction of the muscle around the lesion within it, and it is this type of case which provides the bonesetter with the possibility of a dramatic cure by manipulation.

Muscle, like all tissues of the body, depends upon function for its well-being. It is unfortunate from the standpoint of the treatment that its function is that of contraction. In my opinion massage alone is powerless to prevent wasting of a muscle, or to restore a muscle already wasted. To rest an injured muscle ensures that a fibrous scar will form within it in due course, but at the expense of a wasted muscle. Moreover, the scar may become adherent to neighbouring muscles, or even to neighbouring muscle bundles, and, finally, œdema may persist within the muscle, similar to the œdema which so often persists in fractures of the leg before function is restored.

Active contraction may aggravate a partial tear of muscle—may even increase it. Therefore, if the tear be considerable, it is wise to operate and suture it, so that contraction of the muscle may be commenced sooner than would otherwise be possible. In minor injuries—strains—the harm that contraction does to the lesion is more than compensated for by its prevention of wasting and adhesions, and for this reason strains should be treated by exercises, aided by massage and heat. The harmful effect of the exercises upon the local lesion can be minimised by limiting excessive contraction by strapping.

There are a number of well-recognised conditions which come under the heading of strain, such as tennis elbow (one form at least), tennis leg, cricketer's thigh, and javelin thrower's arm, but I do not propose to describe them here.

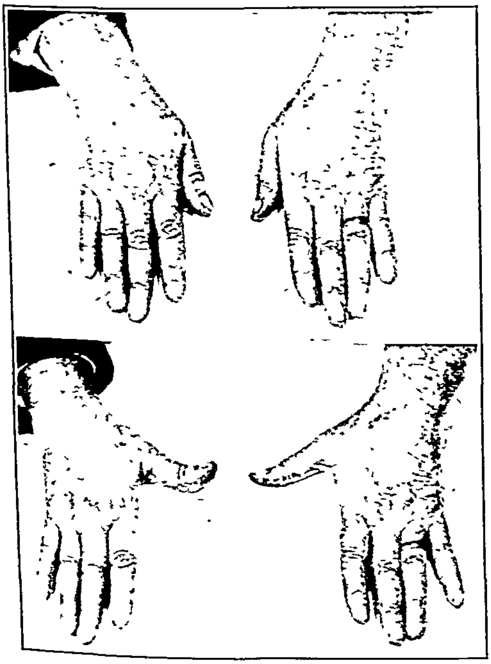
Complete rupture of a muscle or tendon from muscular injury alone is rare, there being only 15 cases out of a total of 18,950 surgical admissions into King's College Hospital. This figure perhaps exaggerates the rarity, as it is probable that a number of the cases seen in the out-patient department were not suited for admission. It has been pointed out that under normal conditions healthy muscle in a healthy subject should not be capable of inflicting injury upon itself. Predisposing causes must be looked for therefore in local conditions of the muscle and tendon, the general condition of the patient, and abnormal circumstances of contraction. Such factors may either diminish the threshold violence for rupture, or momentarily increase the contractile force of the muscle beyond its tensile strength.

LOCAL ABNORMALITIES OF MUSCLE AND TENDON.

Zenker's degeneration of enteric fever, which predisposes to rupture of the rectus abdominis, is well known. Ruptures of this muscle may also complicate severe influenza, as Abrahams and others [4] have shown. The degeneration of muscle in this disease is of a different type from Zenker's.

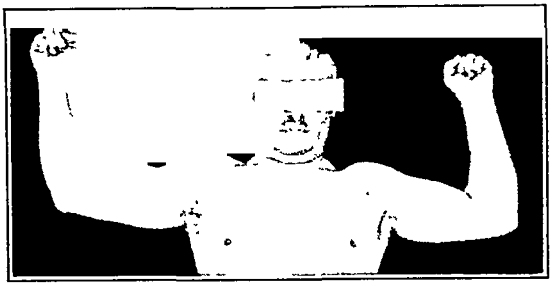
It is exceptional to find primary disease in a tendon predisposing to rupture. Melchior [5] describes a case of rupture of the finger extensors due to gonococcal tendovaginitis. In the museum of the Royal College of Surgeons of England there is a specimen showing gouty deposits within the long flexor to a finger near its insertion. It is conceivable that such deposits may give rise to necrosis, which will lead to rupture.

FIG. 6.



The most striking example of pathological rupture of a tendon is that of the long tendon of the biceps in arthritis. A man of 54 had attended King's College Hospital with painful arthritis of the right shoulder for 18 months. There was little to see in the radiogram. Three days before the photograph (Fig. 5) was taken a lump suddenly appeared in the arm without any sudden symptom suggesting rupture by violence. The lump is the belly of the biceps occupying a lower position in the arm following rupture of the long tendon. Meyer [6] has investigated the pathology of rupture of the long tendon of the biceps in dissecting no less than 13 specimens obtained post mortem. In these cases the disability is not great, and the distal portion gains reattachment to the humerus in the neighbourhood of the bicipital groove. No attempt at operative repair is advisable.

FIG. 5.



Rupture of the long tendon of the right biceps secondary to arthritis of the shoulder.

Previous injury may be a predisposing cause, the muscle or tendon being partially ruptured by this injury, the rupture being completed by a similar type of injury at a later date. In the case of tendons, the injury may cause degenerative changes which lead later to spontaneous rupture. The most striking example of this is rupture of the extensor pollicis longus after injury about the wrist-joint. The injury is usually a Colles fracture, but not invariably, for it may follow simple sprains of the joint. I am indebted to my colleague Mr. St.J. D. Buxton for permission to describe the following example.

A woman of 45 years sprained her wrist. Six weeks later she noticed that she could not extend her thumb. Operation showed a gap in the extensor longus tendon, bridged across by fibrous bands at the distal margin of the posterior annular ligament. Direct suture was possible, and a good result followed. Fig. 6 shows the condition two years later. Movement is perfect except that hyperextension to the degree possible by the right thumb is not present.

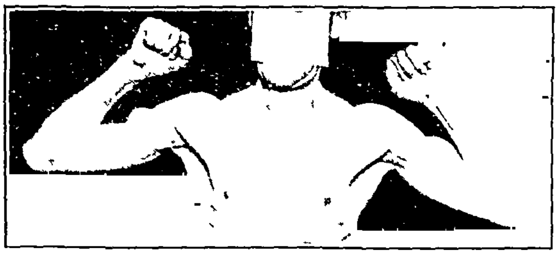
There is considerable microscopic evidence,[7] obtained at operation upon such cases, that the predisposing cause generated by the initial injury is a hyaline degeneration in the tendon, though it does not appear to have been proved whether such degeneration is the cause or the result of the complete rupture of the tendon. The break in extensor longus pollicis always occurs at or near the distal margin of the posterior annular ligament. This site of election is undoubtedly due to the abrupt change of direction of the tendon at this point when the wrist is dorsiflexed.

A history of previous injury is sometimes present in other ruptures, for example, the long head of the biceps, and Mr. H. A. T. Fairbank, who has kindly furnished me with the notes of several private cases of muscle rupture, permits me to mention the following example.

A man of 25 felt something go in the left arm when tackling a man at rugger. A bruise appeared to the outer side of the biceps. The arm got well, but showed some deformity.

Five weeks later the history repeated itself, and when seen three weeks afterwards it was obvious that the long tendon of the biceps had ruptured. At operation the long tendon was found curled up in a mass at the upper part of the fleshy belly, and was so firmly matted that no attempt was made to unravel it. It was sutured to the groove and adjacent tendons. The operation was completely successful and the patient, who had been an Olympic swimmer, was chosen to play water polo for his county four months later.

FIG. 7.



Apparent rupture of the tendon of insertion of the right biceps in a tabetic.

Finally, occupational strain may predispose to rupture, as instanced by the Trommlersehne—drummer's rupture—of German literature.[7] The rupture is of the extensor longus pollicis, at the site of election already described. Other muscles and their occupational predispositions, as stated by various authors, are as follows :—

Thigh adductors in swimmers and riders.
Rectus abdominis in cavalrymen.
External oblique in reapers.
Pronator radii teres in lanceplay (javelin thrower's arm, an example of which is included in the King's College Hospital series).
Pectoralis major in climbing. The one case of rupture of this muscle in my series was sustained by a boxer, who over-reached on driving a right-handed punch at his opponent, who eluded it. The rupture was a partial one.
Biceps in glass blowers.

The contention that the wearing of high heels predisposes to rupture of the tendo Achillis is not borne out by the sex-incidence of this injury.

GENERAL CONDITION OF THE PATIENT.

Like bones, muscles and tendons appear to be more susceptible to injury as age advances. When a man past the athletic age indulges in some violent form of exercise, such as running the hundred, he puts a severe strain upon the integrity of his muscles and tendons. With one exception, all the cases of rupture of the quadriceps in King's College Hospital were over 50.

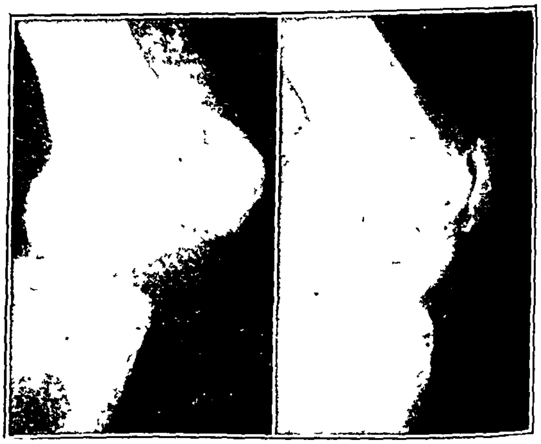
Many diseases are quoted as predisposing causes—arterio-sclerosis, rheumatism, typhoid, alcoholism,[8] and diabetes,[9] to mention a few, but there is lack of clinical evidence. Tabes dorsalis appears to affect tendons in the same little understood way that it does bones. Fig. 7 illustrates the case of a man of 50, who has been under treatment for four years for tabes.† He has been a boxer, hence his excellent physique. The lower tendon of the right biceps appears to have ruptured, but clinical examination shows it to be intact, but stretched. No scar can be felt. It gradually got like this, there having been no causal injury.

ABNORMAL CIRCUMSTANCES OF CONTRACTION.

How can we explain those cases of rupture of muscle and tendon in healthy subjects ? The rarity of muscle rupture, even in the violent contractions of tetanus, supports the view I have already p forward, that healthy muscle in a healthy subj does not rupture from muscular violence alo Some abnormal circumstance of contraction mu be present, and this is usually created by the eleme of surprise, or fear, which may cause a brisk co traction of the muscle, which is entirely unconscio and involuntary. The surprise element may te porarily inhibit control, and the intensity of t contraction may be of itself sufficient to cause ruptu Such a surprise contraction may occur to preve falling. The usual mechanism of rupture of t quadriceps is an example of this. A man comi downstairs slips as he placed his left, say, heel the step in front. In order to prevent himself falli backwards, he involuntarily contracts the quadrice of the leg behind (the right) to the full extent of i power, and this contraction, coupled with the weig of the falling body upon the bent right knee, resu in rupture of the right quadriceps.

Each deliberate body movement is carried out a synergic group of muscles. If, because of fe or surprise, one muscle involuntarily attempts execute a movement ordained to be carried out the group of which it is a synergic member, it ma prove too feeble and break. Again, during forcef contraction of a muscle, or muscle group, to achie some object, a sudden emergency situation ma *arise which causes the antagonists to contract* brisk and involuntarily. This prevents the moveme first started, and the muscle may rupture. Th mechanism of contraction may be at fault. A musc which normally acts *from its origin may* sudden be called upon to reverse its action. The profession gardener is maintained in a stooping attitude throug out the working day by contraction of the rec abdominis, acting from the origin. He may ruptu these muscles if he suddenly calls upon them reverse *their action, as, say, in vaulting into* th saddle. Lack of habit is another factor. Recruit suffer injuries to muscles from comparatively trivia causes, which leave the trained soldier unscathed It is well recognised by the management of profes sional football teams that it is an economy to spar no expense in the training of their teams, as th sick list from injury is thereby immeasurably reduced

FIG. 8.



14.1.26. 3.iv.30.

Rupture of quadriceps. Appearance before and four years after operation.

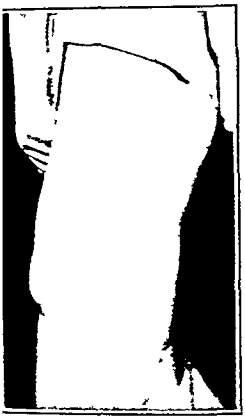
---

† I am indebted for this case to Dr. Macdonald Critchley.

he following illuminating sentence of Ombredanne[1] an excellent summary of this aspect :—

> "Somme tout, manque d'habitude de l'individu et anque d'habitude du muscle pour produire un mouvement inaccoutumé sont les causes premières de cette contraction anormale, incoordonée. déreglée, exagerée, qui aboutit à la rupture."

FIG. 9.



These explanations cannot be applied perhaps to all cases. and at best only touch upon a very complicated and elusive subject. A study of the mechanism of muscle rupture will, however, show that the element of surprise is usually a prominent feature.

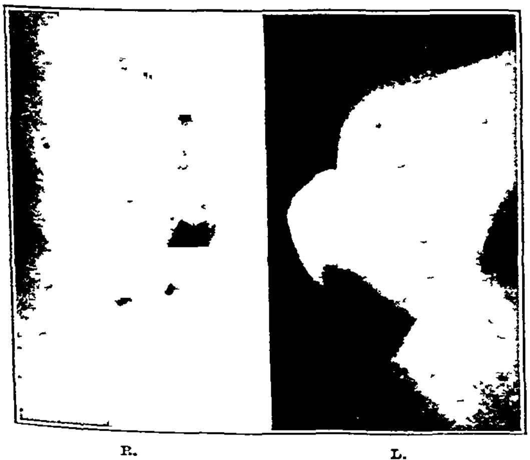
RUPTURES OF SPECIAL MUSCLES.

The commonest ruptures are of the rectus femoris, the biceps humeri, and the tendo Achillis.

The *rectus femoris* has two sites of election : a high one at the junction of the muscle-fibres with the tendon of insertion, and a low one at its insertion into the patella. In the latter injury the lateral expansions might also be involved to a varying extent. The low rupture is the more serious lesion and always demands operation. Not infrequently the torn muscle carries away with it a small fragment from the upper margin of the patella, and this is all to the good, as it makes suture easier.

Fig. 8 shows an example of this injury in a man of 51, who slipped on a wet floor. The right leg went forwards, and the left quadriceps contracted to prevent falling. The left foothold also gave, and the foot slid backwards until it was arrested by coming into contact with a wall, and the rectus ruptured at its attachment to the patella, taking away a flake of bone. There was an interval of two months between the accident and operation. Four years later a small gap could still be seen between the small fragment of bone and the patella. but the functional result is excellent.

FIG. 10.

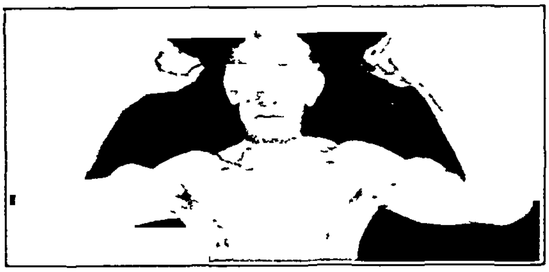


Rupture of the right infrapatella and tendon five years after operation. Note the difference in level as compared with the uninjured side (L.)

Operation is advisable in recent cases of rupture of the rectus femoris at the musculo-tendinous junction, but is not essential, and in late cases should certainly be left, for the rest of the quadriceps compensates for any loss of power, and there is very little disability. Operation in late cases is not easy because of the difficulty in obtaining a suture hold in the muscular (proximal) portion. I should deprecate any attempt to restore the muscle by placing a fascial graft in the gap in late cases, for the muscle will have undergone shortening.

Fig. 9 shows this type of rupture in a man of 20, who ran up against a heavy opponent at rugger. He tried to bend the knee and felt something give. He has a somewhat confused memory of the accident, and the exact mechanism of the rupture is not clear. The illustration was made five months after the accident. It is now 18 months since the rupture, and the function of the leg is good, the patient playing rugger regularly without any appreciable handicap.

FIG. 11.



Rupture of the tendon of insertion of the biceps. Appearance two years after operation.

Infra-patellar tendon rupture is a rare injury and calls for early operation, which may be a matter of considerable difficulty, as the tendon usually ruptures near the bone. Gallie[10] recommends a reconstruction operation, using a slip from the tendo Achillis tendon, and has secured good results by his method in both early and late cases.

The case illustrated (Fig. 10) was that of a man of 52, who fell out of a trap and hyperflexed the right knee. At operation it was found possible to suture the tendon directly, and the result five years after operation is shown. Movements are full, but the muscles are weak and tire easily. The patella is higher on the affected side by ⅝ths of an inch. This is due to stretching of the scar, in which some ossification has taken place.

The poor result obtained in this case is an argument in favour of the routine use of Gallie's operation for rupture of the infra-patellar tendon.

The *biceps* may rupture in any part of its course, and cases have been reported of rupture of the long tendon above the bicipital groove, in the groove, at the musculo-tendinous junction. through the belly, and of the tendon of insertion. Rupture of the short head may also occur. With the exception perhaps of the last named, operation is indicated in all cases in which there are no local predisposing causes. such as arthritis of the joint, but care must be taken in giving a prognosis in rupture of the long tendon cases who are unsuited to, or refuse operation, for the short head of the biceps is capable of considerable compensatory hypertrophy, and the resulting loss of function may ultimately be very slight.

Fig. 11 illustrates a case of rupture of the lower tendon of the biceps two years after operation. The patient is a man of 50, and was lifting a relative, who was having a fit, on to a couch. The body lay across his forearms held in full supination. As he lifted his burden. it suddenly started to slip, and he gave a sudden and involuntary lift up with the right arm and felt something give. At operation three days later the lower tendon of the biceps was found retracted and coiled up. having ruptured near its insertion into the radius. The proximal end was sutured to the supinator brevis fascia. As is evident from the illustration, the scar has stretched, but function is good. He can carry heavy weights with the arm, and his only complaint is that he cannot use a walking stick.

Rupture of the *tendo Achillis* appears to be most common where the muscle-fibres end, which is the narrowest portion, and about 1¾ in. above the os calcis. The plantaris may rupture with it. It is surprising how trivial may be the cause of rupture of the tendo Achillis in older subjects. A man of 63 felt something give at the back of the right leg when stepping off a low curb, and a violent pain in the calf, as though struck from behind with a stick. Operation showed a complete tear of the tendon. The optimum treatment in all cases of complete rupture of this tendon is undoubtedly operation, and the case for conservative treatment is largely a relic of pre-Listerian days.

Partial rupture of the *gastrocnemius* is the usual form of tennis leg, and should be treated on the lines already suggested for minor injuries. The at-one-time popular theory that tennis leg is due to rupture of the plantaris tendon can, I think, be completely discredited, in view of the absence of any shred of evidence, either clinical or pathological, in support of it.

Riders' rupture—rupture of the *adductor longus*—varies from a tearing of a few fibres to complete rupture of the muscle at its insertion into the femur. Occasionally the adductor brevis ruptures, but rupture of the adductor magnus is rare. Operation should not be attempted even in complete ruptures of the adductor longus, as the break occurs so close to the bone that repair is practically impossible. Very little disability results from the injury, although excision of the muscle tumour caused by the loss of its insertion may be necessary at a later date.

Rupture of the *hamstrings* is rare, but through the courtesy of Mr. Fairbank I am able to describe the following case of complete rupture of the semi-membranosus in a man of 20.

> There was a double injury at an interval of three years, both sustained at Rugby football. On the second occasion the patient was tackled by the left ankle, and felt something go above the left knee. At operation five weeks later, a scar was found in the semi-membranosus, with the healthy muscle belly below. Above the scar there were some pale, paralysed fibres, and above this again a short portion of healthy muscle. The scar was freed, divided, overlapped, and sutured. The belly of the muscle was sutured to the healthy fibres above. Ten months after operation the patient reported that he was playing Rugby again without any disability.

Ruptures of the *rectus abdominis*, apart from disease, are of particular interest because in a few cases operation has been performed on a diagnosis of acute appendicitis. The lesion in the muscle is usually a tear near its origin from the pubis. There is pain and tenderness to pressure, with local resistance and a tendency to nausea. The rupture occurs as the result of some sudden strain referred to the abdomen. Behan[11] describes the case of a patient who suffered this injury from opening a window with a jerk.

Mention must be made of muscle and tendon lesions around the shoulder-joint, which may be a cause of persistent shoulder pain after injury. The *supraspinatus* tendon appears to be the most frequently injured. Codman[12] states that he has no difficulty in finding a complete or partial tear of this tendon in the dissecting-room, and puts the incidence at 1 in 20 of the bodies dissected. This is certainly much higher than the clinical evidence in this country leads us to believe. Injury of the tendon is related to subdeltoid bursitis, and the physical sign of crepitus may be elicited. The two cases which I have seen of subdeltoid bursitis following injury, one in a rheumatic subject of 43 and one in a healthy girl of 22, both got well with physical treatment. In neither of these cases was there any X ray evidence of the presence of calcareous deposits about the tendon that sometimes complicates the injury.

Open Wounds of Tendons.

I shall confine my remarks to open wounds of the finger tendons, a subject which I conceive to be of very great economic importance. Table I. indicates the relative frequency of open divisions of the extensors and flexors of the fingers.

TABLE I.

—	Wrist.	Dorsum.	Thumb.	Fingers.	Total.
Extensors	10	13	2	27	52
Flexors ..	25 8 unaccompanied by nerve injury.	Palm. 11	4	11	51
			Total ..	..	103

Taken as a whole, wounds of the extensors do well after suture, but wounds of the flexors badly. How badly is shown by the figures in Table II.

TABLE II.—*Results in 34 Cases of Cut Flexor Tendons.*

—	No.	Good.	Fair.	Bad.	Untraced.
Wrist	8	4	2	2	0
Palm	11	2	2	7	0
Fingers	11	0	0	5	6
Thumb	4	0	2	2	0
Total ..	34	6	6	16	6

Out of 28 cases traced, therefore, the results are as follows: good, 21 per cent.; fair, 21 per cent.; bad, 58 per cent.

This summary of results agrees in the main with other authentic statistics.[13] The difference in prognosis between the extensors and flexors is due to the presence around the latter of a synovial sheath with its delicate gliding mechanism. The cause of the failure in all cases was the formation of adhesions in and about this sheath, so that the tendon was anchored. If one knew how to prevent adhesions, good results could be obtained. What are the predisposing causes of their formation? I think they may be summed up as sepsis, bad operative technique and prolonged immobilisation.

Sepsis.—Our control over sepsis is a limited one yet much can be done to counter infection. Many of the cases included in Table II. were sutured in a casualty department immediately, under the mistaken view that urgency is essential. Such is not the case. The only two perfect results of division of the flexors in the palm were both sutured in the operating theatre three days after the injury, and after careful preparation of the skin. To minimise sepsis, therefore, operation should not be regarded as an emergency measure, but should be performed under ideal conditions after routine preparation of the skin.

Bad Technique.—The operation is not one really suited to resident hospital officers, but calls for experienced work. The actual method of suture is of extreme importance, the aim being to obtain as small a scar as possible. The method of "buried suture" suggested by Bunnell[14] is probably the best, the knots of the suture being brought to lie between the divided ends of the tendon.

Prolonged Immobilisation.—If accurate suture is achieved, there should be nothing to fear from early movement, which may be commenced the next day. The movement must be active or assisted, for passive movements alone have absolutely no power to prevent adhesions. A splint must be worn except during treatment to prevent the tendency to flexion deformity, which is apt to occur. Finally, apart from the prevention of adhesions, movement is important in that by its means correct orientation of the scar in the tendon may be obtained from the outset.

THE MECHANISM OF DIASTOLIC BLOOD PRESSURE.

A NEW CONCEPTION.

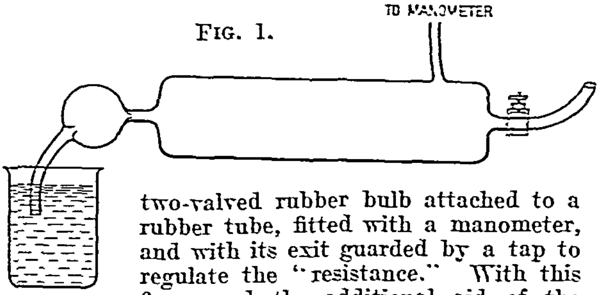
BY C. B. ROSSITER, M.D. DURH., F.R.C.S. EDIN.,
FORMERLY HON. PHYSICIAN, AUCKLAND HOSPITAL, N.Z.

I PRESUME that the apparent simplicity of the conventional theory of the production of diastolic pressure, and the lack of any obvious alternative, is the reason for its appearance without material alteration in successive generations of physiological text-books ever since diastolic pressure became an accepted clinical fact. But anyone who, like myself, studies the literature of the subject, cannot avoid being impressed by the fact that physiologists, in assuming its accuracy, have frequently had great difficulty in satisfactorily accounting for circulatory phenomena. Their explanations have, indeed, been ambiguous and confusing. The purpose of this paper is to demonstrate that there may be another, and almost equally simple mechanism, which can account for all the associated clinical facts, and suggest solutions of problems which the other cannot solve.

The hydrodynamics of the circulation being a vast and intricate subject, I must try to set out my views as briefly and simply as possible, the facts on which they are based being more fully set forth, although differently interpreted, in the standard physiological text-books. Unfortunately these books only describe the mechanism of the circulation as it is believed to function in the fully developed adult anatomical "unit." For instance, the statement is made that the heart is a prime cause of blood pressure; whereas it is patent that pressure exists in the earliest embryonic days before the heart is formed. Embryological works are likewise disconcertingly silent or vague on the manner in which blood-vessels develop during the first few days after fertilisation of the ovum. So far as I am able to conceive of the sequence of pressure development, from the birth of the circulation, it leads me to an impasse if I accept the customary view, but easily fits in with the idea I am about to expound. For instance, how does the pressure start from zero and finally stabilise at the normal terminal diastolic pressure? But perhaps it were fitter that I should do no more than hint at the profound readjustment of orthodox views necessary should my theory be valid, and without further generalisations proceed to develop my argument.

Fig. 1 shows a piece of apparatus consisting of a two-valved rubber bulb attached to a rubber tube, fitted with a manometer, and with its exit guarded by a tap to regulate the "resistance." With this figure and the additional aid of the graph, Fig. 2, I can demonstrate most of the points I wish to make clear.

FIG. 1.



THE CONVENTIONAL THEORY.

In the first place, for the sake of comparison, let us consider very briefly the mechanism of the conventional theory.

Fill the apparatus with water so that it is just about to escape from the up-tilted nozzle tip, and the intratubal pressure will be slightly above zero. For practical purposes, however, we may call it zero. We will assume that the capacity of the bulb is 65 c.cm., and that owing to the size and resiliency of the tube, and adjustment of the tap, if we empty the bulb by squeezing it in 0·3 sec., the manometer will show a rise of pressure to 50 mm. Hg. If the tube is then allowed to discharge its excess volume until zero pressure is reached, and the status quo ante is attained, the time required from the termination of the bulb compression to this point will be, say, 2 secs. ("diastolic period"). But at the expiration of 0·5 sec. the pressure will only have fallen to say, 30 mm. Hg. A total period of 0·8 sec. having therefore by now elapsed since we began to squeeze the bulb, we repeat this procedure, but owing to the additional volume and pressure in the tube we shall require extra force to overcome the resistance in 0·3 sec., and at the expiration of a further 0·5 sec. the pressure will be higher than at the end of the first "cycle," although the water has been escaping at a faster rate. After an indefinite number of these 0·8 sec. cycles, equilibrium is supposed to be established, and the intratubal pressure can be imagined to have been stabilised as we find it actually to exist in the human circulation and depicted on the graph (Fig. 2, NSEFMN).

OBJECTIONS TO THE CONVENTIONAL THEORY.

At this point I think it would be well that I should briefly indicate some of the more obvious objections suggested by this mechanism.

1. It is difficult to conceive how analogous conditions could obtain in the real circulation, during its birth.

2. It is pure assumption that the arteries really are distended at the end of diastole, their calibre at zero pressure never having been measured.

3. It is implied that the arteries are always distended by a pressure of at least 80 mm. Hg throughout life. This entails constant histological distortion of the walls, which by analogy with other vital tissues should result in structural change of a permanent and injurious character. Physiological activity requires proportionate rest.

4. A great part of the heart's energy is absorbed in overcoming the already partly distended arteries. If

it can be shown that it is possible to have the same clinical pressure readings, even if the vessels are completely relaxed at the end of diastole, so far as their elasticity is concerned, it would support the view that in this case also the conventional idea is unphysiological and unsound.

5. In order to maintain the minimum pressure at the same level at the beginning and end of the cardiac cycle, and also to keep the diastolic pressure within safe limits, very delicate adjustments have to be made between the resistance and the heart-beats, as can be shown by our apparatus. The blood enters the aorta through a sectional area of say, 7 sq. cm., and leaves the systemic arterial portion, through about 9000 millions of arterioles, of a combined sectional area of about 9500 sq. cm. These minute vessels are divided up into numerous groups of varying functional activity—e.g., renal, hepatic, muscular. Physiologists admit that local isolated groups influence the pressure but slightly, if at all. Therefore it is implied that the greater part of all these groups can so coördinate their various functions as to either *permit of a steady heart-rate, or an abnormal one,* without disturbing the pressure. If another factor can be shown to do this in a more practical way this will also help my argument.

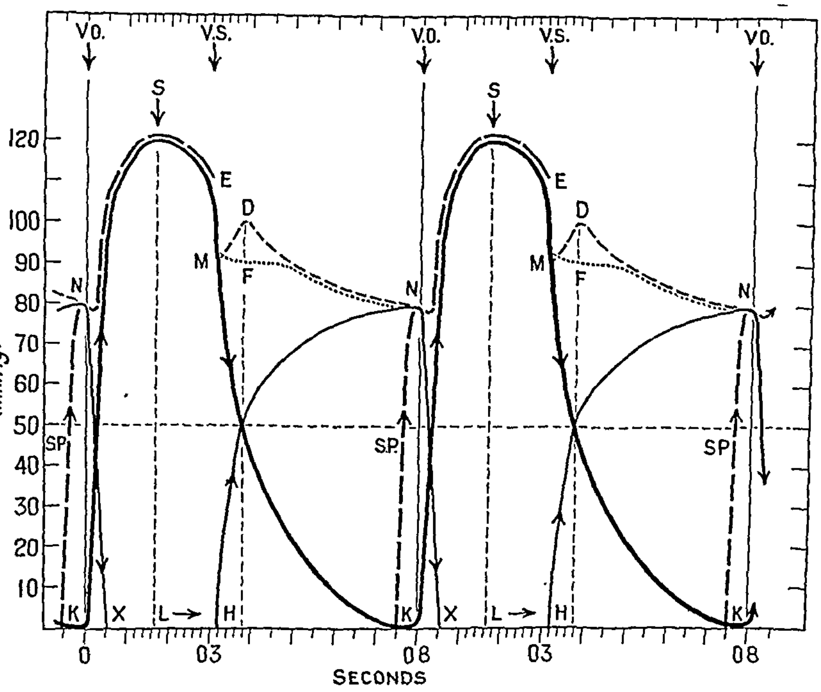
6. The whole burden of propelling the blood during diastole is thrown upon the arterial elasticity under the usual scheme. The internal surface area of the arterial vessels alone has been computed at about 30 sq. metres. It is also estimated that these number about 17,000 millions, of various sizes and tortuosity, and hydrostatic elevation. In addition there is the hydrostatic "head" to be overcome at the arteriolar-capillary junction, representing the "resistance" of the capillaries and veins beyond this. It is immaterial whether the above figures are only approximately correct; surely it might reasonably be expected that a constantly falling "store" of elastic energy would be inadequate for this task, and would be better performed by an active muscular force, as I will suggest. It is useful to recall that the heart, with about 65 beats, passes into the arteries all the blood in the body.

7. The only interpretation—viz., reflux effect—it permits of the dicrotic wave is extremely unsatisfactory (see later). Whereas if the phenomenon be regarded as the signal of the onset of muscular contraction (see graph), this would be strong corroboration of the correctness of my *alternative theory.*

DIFFERENT MECHANISM.

For present purposes this selection of (admittedly controversial) objections must suffice.

FIG 2.



Graph depicting two successive normal heart cycles (0·8 sec.). The upper composite line, NSEMDN, corresponds to normal intra-arterial pressure.
Thick interrupted line, SPNSE = ventricular systolic pressure, reaching maximum at S and ending E. Portion SP = presphygmic rise, which does not affect intra-arterial pressure, merely serving to force valves open at N. V.O. = opening of valves. V.S. = closing of valves.
Thick continuous line = elastic pressure due to varying volume of blood. Portion K (zero) to E = while ventricle is acting. E to M = immediately after valves close. M down to K = curve resulting from added *arterial muscular compression, accelerating* evacuation.
Fine dotted line, MFN = course which would be taken by thick line if no muscular compression was acting.
Thin continuous line = pressure on arterial contents due to muscular coat, starting at H (zero) after latent period L→H, rising to N, where it serves to hold valves closed while SP is rising. Then dropping sharply to X (zero).
Thin interrupted line, MDN = resultant pressure curve of added muscular and elastic effects. D = dicrotic wave. M = incisura.
Note that the vertical line dropped from D intersects elastic curve at 50 mm. Hg, and the muscular at 50 mm. Hg, the total forces acting on arterial contents at this moment being 100 mm. Hg.

Let us now return to our rubber apparatus, the tube of which we will imagine to be of a rather less resiliency than in our first experiment, so that when the same volume as before is injected the pressure will rise to 120 mm. Hg exactly as shown on the graph; falling to 90 mm. at the expiration of 0·3 sec., when the injection ends and the valve closes. *At this point* I am prepared to admit that a very *slight* pressure notch might occur in the real artery owing to the reflux, but the *analogy between the conditions in a rigid tube and an elastic* one, as usually given in the *text-books, is in my humble* opinion misleading. A rigid tube cannot take up the vacuum formed between the tap and receding column of water when the former is turned off, hence the column tends to move back, whereas an elastic tube can at once recoil on the vacuum and so prevent return of water. I shall therefore assume that the falling pressure gradient from here to the end of the 0·5 sec. diastole will not take the form of the dicrotic wave, but follow the line MFN (Fig. 2) just below, until it has fallen to 80 mm. Hg at the end of the cycle. If the bulb were to contract then, the pressure would, of course, rise much higher in the ensuing cycle, if we assume that the sole cause of the diastolic pressure is due to the elastic recoil. Supposing, however, that at the end of "systole" (V.S.) I grasp the *tube* in my other hand and squeeze it with a gradually increasing force, represented in time and degree by the uprising gradient (HN). This force aiding the elastic tension will cause the fluid to be evacuated at a rate and time indicated by the line (MK), with the result that when the end of the "cycle" is reached the "compressional" pressure has risen to 80 mm., but the elastic fallen to zero, and so the artery regained its normal calibre. This cycle can be repeated indefinitely without change. Thus while the "intravascular" pressure has followed the same course as before, its *components* have changed, and the calibre of the artery diminishes faster than under the conventional theory.

Now if it be possible that the muscular coat can act like my fist, the whole scheme becomes feasible in the living circulation. We can assume that at the moment the ventriculo-arterial valves are about to open the arterial pressure is at 80 mm. Hg, not because of elastic tension, but owing to muscular compression, and that as soon as the ventricular pressure has superseded this the arterial muscular contraction rapidly relaxes to zero. This can be effected in our rubber model by retaining the squeeze on the tube with our right hand until the bulb compression is started with our left. This muscular relaxation permits of the *undistended* artery being equally rapidly refilled. The effect is shown in the graph. The ventricle thus injects its contents under the best possible conditions. The slight fall at the beginning of the normal pressure curve (N) may be due to this.

The muscular force starting at H, after a period of rest from X, commences to act on the pressure curve MF at M, and it will be seen that the former rises in about 4/50 sec. to 50 mm. Hg, while owing to the increased rate at which the fluid has escaped during this time, the elastic curve MK has fallen 40 mm. from 90 mm. to 50 mm. Hg. Therefore, as 50+50=100 mm., the original line MF has risen 10 mm. to form the dicrotic wave (D).

When the tube is grasped as described, a bulge will form against the edge of the fist, and if this be slid along the tube, while compressing it, the bulge will advance ahead of it. If an increasing band of muscular contraction were to advance from the root of the aorta towards the periphery a similar bulge or wave would arise and show on a volume tracing like a dicrotic wave. It is obvious that if the artery is in active muscular contraction during cardiac diastole any risk of over-distension is impossible. As the growth of the muscular coat in the embryo would proceed pari passu with the development of peripheral resistance, there is no need to assume terminal diastolic arterial distension at any period of life; hence there is no need to think that arteries are more immune than other tissues to injury from histological distortion.

The usual stimulus to contraction of the involuntary coats of hollow viscera is stretching. The circulatory system is a hollow viscus. It is suitably stretched at each ventricular systole. Assuming it responds by contracting to this, it would do so in proportion to the force of the stimulus and its own irritability. A consideration of this possibility leads one to think that this is a more useful and practical way of controlling pressure than modifications of the arteriolar exit. It also opens up new therapeutic avenues.

GENERAL CONSIDERATIONS.

Is there any experimental evidence that arteries act in this manner? Although for many years I had conceived that this might be possible, it was only about two years ago that I came across a paper published by L. E. Bayliss nearly 30 years ago (*Jour. Phys.*, 1902, xxviii., 231), entitled The Local Reactions of the Arterial Wall to Changes of Internal Pressure. In this he says:—

> "The muscular coats of arteries react like smooth muscle in other situations to a stretching force by contraction . . . this force is myogenic in origin, as this result can be obtained in situ and in excised portions of the arteries. . . . When pressure is suddenly increased the artery appears to wriggle like a worm."

The experiments were performed on dogs' carotids. Those interested should refer to the full text. This seems to indicate that my views are not fantastic.

The latent period of smooth muscle is notoriously slow. The available period on our graph is from the summit of the systole curve to the point where the dicrotic wave starts—viz., nearly 0·2 sec.—which appears to be regarded as the minimum possible for smooth muscle in other localities. The arterial muscle is not quite comparable to, say, intestinal muscle; in certain areas, especially in the large vessels, it approaches the cardiac muscle in type, and possibly the latent period is shorter than imagined. I am not aware of any recent work on the excitability of arterial muscle which necessarily negatives my assumption that the available latent period is sufficient. Further there is some doubt in my mind whether the stimulus should not be regarded as commencing before the systolic summit is reached, and if so the period would be extended. Histologists inform us that the relative amount of muscular tissue in the arterial walls gradually increases towards the peripheral vessels in contrast to the elastic. This should be expected if the stored ventricular energy becomes less effective as the distance from the heart increases and requires muscular reinforcement in the manner I am suggesting.

The dicrotic wave is most marked in the medium-sized arteries, where the muscular action would be most evident and least in the elastic aorta where one would expect a valvular reflux wave to be most marked. Schiff's rhythmic pressure "rises" could be explained as a periodical elevation of the threshold of arterial excitability, although the cause of this periodicity remains uncertain.

The scheme allows for complete elastic relaxation once per cycle, rest for the musculosa during the cardiac systole, and conservation of cardiac energy and histological structure. In view of all the foregoing is it reasonable to assign to the arterial muscular coats no other function but that of maintaining that nebulous state called "tonus"?

When I was a student the idea of active capillary contraction would have been absurd. Veins were, and are still, regarded by clinicians as mere fibrous conduits, although anyone in the habit of injecting varicose veins knows how irritating the active contractile response to the needle can be. Hence the gods may have been caught napping once more; and my view that we must consider the existence of a new and even more important circulatory propelling force than the heart may not be so preposterous as might appear at first sight.

Egham, Surrey.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—King Edward's Hospital Fund for London has received a gift of £10,000 from an anonymous donor, subject to special trusts to be exercised by the King's Fund in their discretion, and under certain conditions, which will be communicated in due course to the hospital or hospitals concerned.

ACUTE RHEUMATISM AND THE SEDIMENTATION RATE.

BY WILFRID W. PAYNE, M.B. LOND.,

BIOCHEMIST TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THE sedimentation rate of the red blood corpuscles varies with the health of the subject. It is no more specific of any disease than is a raised temperature; and, like variations in temperature, it can indicate both the presence of disease and the progress of an illness. The following preliminary note shows how the sedimentation rate changes with the varied progress of acute rheumatism in children.

TECHNIQUE.

In most of the methods for performing this test the quantity of blood required necessitates venous puncture; but as children do not tolerate repeated venous puncture at all well, a simple method was devised requiring only 0·4 c.cm. of blood which can easily be obtained, after a little practice, from one stab of the finger pulp.

The apparatus required is a pipette graduated at 0·1 and 0·5 c.cm.—an ordinary straight 1 c.cm. pipette graduated in 0·01 c.cm. is quite suitable—a small glass capsule or test-tube, a block of wood with a lump of plasticene stuck firmly on it, and finally some thin glass capillary tubing with an internal bore of between 1·6 and 1·9 mm. This is cut into lengths of about 12 cm. and a mark is made exactly 10 cm. from one end.

A solution of 3·8 per cent. neutral sodium citrate in water is the only reagent needed. 0·1 c.cm. of this solution is sucked into the graduated pipette and the finger is then stabbed, the blood is collected straight into the pipette by capillary action until full to the 0·5 c.cm. mark. The citrate and blood are then discharged into the glass capsule, mixed and sucked up into the pipette again. One of the capillary tubes is now stuck horizontally on the plasticene and the blood is run into it up to the 10 cm. mark. Still keeping horizontal the tube is pushed into the lump of plasticene which thus seals the lower end of the tube and without withdrawing the tube from the plasticene it is rotated into the vertical position and the time noted. The level of the blood is now above the 10 cm. mark owing to the plug of plasticene pushing it up. After standing it will be seen that the red cells have fallen leaving a clear column of plasma. The height of this clear column is measured in mm. after one hour and if desired again at 2 and 24 hours. The first hour measurement gives sufficient information, but in severe cases the reading at the end of half an hour is instructive. The reading at one hour is normally from 3 to 6 mm. and values over 10 mm. can be considered abnormal.

The following precautions must be observed:—

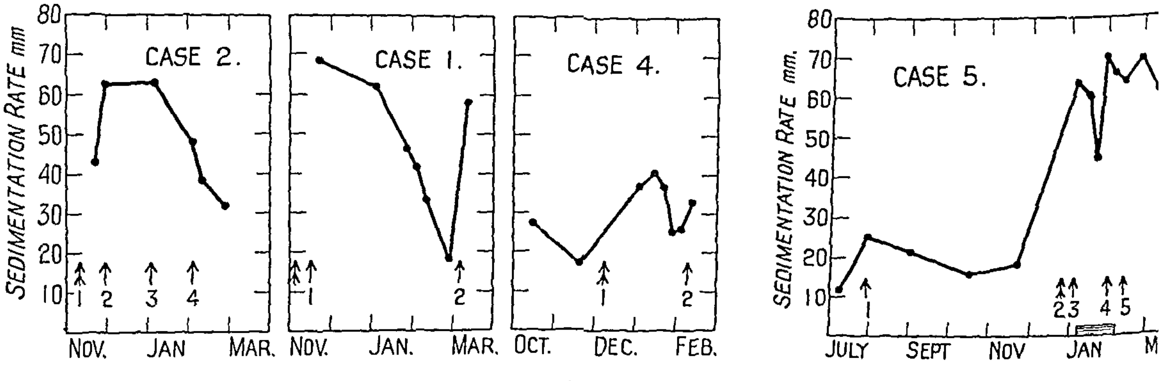
Temperature.—The optimum temperature is about 18° C., the rate of sedimentation increases with rise of temperature but only slowly up to 25° C., after which a more rapid rate of increase begins. It is sufficient to keep the tubes standing away from sources of heat and in summer to place them in a shady cool con of the room.

Position.—The tubes must be kept vertical af setting up. If it is necessary to transport the blo it is well to do so in a small stoppered tube af mixing with citrate and to put it into the capill tube later. This will not alter the result provid the delay does not exceed five to six hours.

Glassware.—The collecting pipettes should cleaned in the same manner as a blood count pipet the capillary tubes cannot be satisfactorily clea and are discarded. It is important to avoid dust grease as these are liable to cause air bubbles in capillary tube which must be got rid of.

RATIONALE.

While the variations in viscosity and spec gravity of the plasma have some small effect, two most important factors involved are the num of red cells and the protein content of the plas Anæmia will cause an increased rate of sedimentati as can be shown by diluting the blood with its o plasma; but given a normal number of red c the plasma is the controlling factor. The sa washed red cells will sediment rapidly in plas obtained from a diseased person and normally normal plasma, providing no agglutination occ from incompatibility. The rate of sedimentation i suspension such as red cells in blood depends larg on the size of the particles involved—e.g., mist a rain—and anything that causes the red cells agglutinate and form larger units increases the r of sedimentation. Broadly speaking, anything t allows the red cells to lose their electric charge allow them to agglutinate. The plasma fibrinogen a to a lesser extent the plasma globulin are both prote which tend to allow the red cells to discharge th electricity but the plasma albumin acts in an oppos manner. An increase in the fibrinogen or a decre in the albumin-globulin ratio will therefore tend increase the sedimentation rate and one or both these changes are usually found in practice when sedimentation rate is increased. It is probable t the site of these changes is in the liver, which is t sole source of fibrinogen and probably the m source of the other plasma proteins and also of t circulating antibodies which are linked with t euglobulin fraction of the plasma.

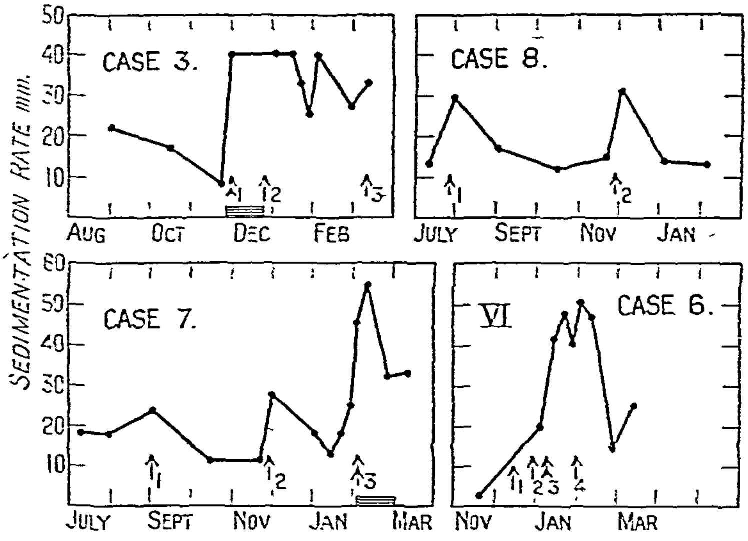


RESULTS.

Dr. W. Sheldon and Dr. W. R. F. Collis ha recently reported[1] an epidemic of tonsillitis in group of children convalescing from rheumatic fev It so happened that a series of sedimentation te were being made at the hospital at that time and t opportunity was taken to follow up some of the cases infected. The following cases, illustrated in the Charts, are selected from the series showing the results obtained. The arrows represent points of clinical interest (usually febrile disturbances). The double-headed arrows represent the "initial fever" in Sheldon's table. The shaded area represents the periods during which aspirin was given.

---

[1] THE LANCET, 1931, i., 1337 and 1341.



CASE 1 (Sheldon's Case 19).—Period 0–1: sore-throat, Oct. 11th, 1930; tonsillitis, Nov. 1st, and fluctuating temperature. Point 1: pericarditis. Period 1–2: progress steady; pulse-rate falling. Point 2: temp. 101° F.: pulse-rate rising: throat red; bronchitis.

CASE 2 (Sheldon's Case 20).—Point 1: tonsillitis: temp. 101° F.: pulse-rate raised. Period 1–2: quiescent; pulse lower: temp. normal. Point 2: relapse; temp. 101°: pulse-rate raised. Period 2–3: two attacks of fever with lung involvement. Period 3–4: no further attacks, but occasional slight rise of temp.; pulse-rate falling. Period 4 onwards: slow improvement.

CASE 3 (Sheldon's Case 23).—Point 0–1: doing well: *temp. normal*: pulse-rate becoming steadier. At 1: sore-throat; aspirin grs. x. t.d.s.: temp. 102°: pulse-rate raised. Period 1–2: temp. normal; pulse-rate as in period 0–1. Point 2: aspirin omitted: pulse-rate rose: nodules developed; no carditis. Period 2–3 onwards; pulse-rate more rapid than in period 0–1 but steady progress made. Point 3: slight pyrexia.

CASE 4 (Sheldon's Case 26).—Period 0–1: steady improvement; temp. normal; pulse-rate falling. Point 1: tonsillitis; temp. 102° F.; pulse-rate up. Period 1–2: no relapse; steady improvement. Point 2: rise in pulse-rate, cause.

CASE 5 (Sheldon's Case 28).—Period 0–1: very slow improvement. Point 1: unexplained slight pyrexia. Period 1–2: slow improvement. Point 2: rise of temp. Point 3: further fever; carditis developed; aspirin started. Period 3–4: quiescent. Point 4: rise of temp. Period 4–5: slight intermittent fever and temp. 99° F. Point 5: temp. 101°; aspirin omitted few days before. Period 5 onwards: intermittent temp. 100·5°.

CASE 6 (Sheldon's Case 29).—Period 0–1: condition improving. Point 1: slight fever. Period 1–2: quiescent. Point 2: relapse: temp. 101° F.; pulse-rate raised: pain in knee. Period 2–3: quieter. Point 3: temp. 101°; throat red. Period 3–4: temp. normal: pulse-rate a little higher than period 0–1. Point 4: temp. 101°; pains in forearms; pulse-rate unchanged. Period 4 to end: temp. normal: improving; pulse-rate falling.

CASE 7.—Aortic and mitral disease. Period 0–1: settling down after several relapses. Point 1: erythema marginatum; slight temp. Period 1–2: progress good except for a few days unexplained rise of pulse. Point 2: slight temp., 99·4° F., for several days. Period 2–3: progress maintained; sitting up. Point 3: temp. 103°; pulse-rate raised; throat red but not sore; aspirin. Period 3–4: no further fever; pulse-rate falls until aspirin omitted, when rise occurred.

CASE 8.—Mitral and aortic disease. Period 0–1: steady improvement since February, 1930. Point 1: slight unexplained rise of temp., 99°, and rise of pulse-rate. Period 1–2: steady improvement. Point 2: slight fever; slight rise of pulse-rate. Period 2 and onwards: doing well.

It will be seen that there is a close relation between the clinical findings and the sedimentation rate. Almost every variation in the sedimentation rate can be shown to have a corresponding clinical counterpart. In three of the cases aspirin was given; as pointed out by Sheldon, in this series some of the cases receiving aspirin appeared to have been benefited by it, but on leaving off the drug the pulse-rate rose and further cardiac damage was manifest. It will be seen that in two such cases (Nos. 3 and 5), although there was temporary clinical improvement, no improvement in the sedimentation rate was shown.

In practice the test is of use in several ways. The most obvious and probably the most useful is in gauging the progress of a patient, especially in diseases of long duration such as rheumatism and tuberculosis. It gives a reliable numerical index to the progress, good or bad, and thus enables a more certain valuation to be made of the efficacy of any line of treatment. Again its failure to return to normal gives an indication of the persistence of some active pathological process. It is hoped that as more data become available the sedimentation rate will prove to be a useful guide in determining the presence or absence of an *active* cardiac lesion. Also in the after-care of these children it should give an early indication of impending trouble.

My thanks are due to Dr. Collis and Dr. Sheldon for their cordial coöperation, to Dr. Sheldon for granting me access to his cases and notes at Cheyne Hospital, and especially to the sister and staff of the ward at Cheyne Hospital in which the work was done for the considerable amount of help they have given me.

ERYTHROCYTE SEDIMENTATION RATE IN RHEUMATIC FEVER.

BY FRANCIS BACH, M.D. OXF.,
CHIEF ASSISTANT, CARDIOGRAPHIC DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL; CHADWICK TRAVELLING SCHOLAR;

AND

N. GRAY HILL, *M.C.*, M.B. LOND., D.P.H.,
DEPUTY MEDICAL SUPERINTENDENT, QUEEN MARY'S HOSPITAL, CARSHALTON.

RHEUMATIC fever may be looked upon as a specific disease which may manifest itself to the clinician in several ways. It may appear as acute rheumatic arthritis, chorea, rheumatic carditis, and in many other less easily recognisable forms. The clinical diagnosis may be difficult, and is dependent on the elucidation of rather indefinite symptoms and signs. In any particular case when the diagnosis has been made, the line of treatment that is indicated depends on whether or not the disease is "active" or quiescent. There are certain investigations which are of value in making and substantiating the diagnosis of the disease, and are of assistance in following its course.

Amongst these the weight, the temperature, and the pulse-rate, the blood leucocyte count, the electrocardiographic finding, and the erythrocyte sedimentation rate are of real interest. It is in connexion with the last of these that the present paper is written.

In 1917, F. Fahraeus, a Swedish physician, discovered that in blood withdrawn from a vein and prevented from clotting the erythrocytes form a sediment more rapidly when certain pathological conditions are present than in the blood drawn from a normal person. Alteration of the sedimentation rate is thought to result from changes in the chemico-colloidal conditions of the blood depending upon the percentage of globular fibrinogen, and probably also the lipoids that are present.

THE INVESTIGATIONS.

We have carried out a series of investigations on certain children under treatment for juvenile rheumatism at Queen Mary's Hospital, Carshalton. We have applied the E.S.R. test to a number of children in the wards of the hospital. The test was done during the day. The technique was simple, and was as follows :—

From the child lying in bed 1 c.cm. of blood was withdrawn from a vein in the arm, added to 0·2 c.cm. of sodium citrate, well mixed, and then drawn up into the Westergren apparatus, which consists of special capillary tubes (2·5 mm. in bore) held vertically in a special stand. The tubes were then left at room temperature in the ward. At the end of one and of two hours the degree of sedimentation was ascertained by reading the lower level of the clear supernatant fluid. The figures indicate the length of a column of clear plasma above the settled erythrocytes, the end point being, in practice, a clear-cut line.

In our experience the figures for normal people are usually under 10 mm. at the end of the first hour and under 20 at the end of the second hour, though distinctly lower readings are usually met with in healthy persons.

The cases in col. 1, Table I., with readings higher than 30 for the first hour, 60 for the second hour, were all cases exhibiting definite and unquestionable evidence of active rheumatism ; almost all had some degree of pyrexia, and showed such signs as a pericardial rub, severe chorea, or developed rheumatic nodules, if the more classical picture of acute juvenile rheumatism was not present. The cases in col. 3 and 4 with readings of 7 for the first hour and 23 for the second hour and less were, with two exceptions, regarded as quiescent. Most of these cases were known to have been definitely active at some previous date, or showed signs of cardiac damage strongly suggestive of previous rheumatic infection.

The cases with readings of less than 30–60 for the first and second hours respectively were, on the whole, cases that would be regarded as quiescent when examined, but amongst them there were a relatively high proportion of patients who were not making very satisfactory progress, were not gaining weight or, generally, doing so well as those in cols. 3 and 4.

Table II. has been compiled to show the type readings that we obtained.

The cases in Table II. are divided into two group —Group A, those that were "active" at the com mencement of the investigation and tended to becom "quiescent" ; and Group B, those that appeare to be "quiescent" throughout. Two cases may b recorded as typical.

CASE 1.—A boy, aged 13, began to have rheumatic pai about 14 weeks before admission, and definite chor about ten days before admission. When he was examin on Dec. 23rd, 1930, the chorea was of a severe type, ar

short blowing systolic murmur was found to be present t the apex. The sedimentation readings for January and February were 55–67 and 48–75 respectively. The condition hen improved, and by March the patient was free from horea and had gained about half a stone in weight. During he remainder of his stay in hospital he made satisfactory progress, and the sedimentation rates remained low.

Case 2.—A boy, aged 12, had a history of recurrent attacks of acute rheumatism, almost yearly since 1923, or which he had received a certain amount of hospital reatment. On admission in November, 1930, the temperature was 103° F., both knees were swollen and painful, and the ankles and wrists had been swollen during the 24 hours prior to admission. There were signs of endocarditis, probably of long standing. A pericardial rub was present a few days after admission, and the sedimentation rate taken about a fortnight after admission was 80–124. There was a fairly steady improvement in this boy's condition, and a steady gain in weight. This was accompanied by a fall in sedimentation rate. The pericardial rub was of short duration, though the murmur of valvular origin remained unchanged throughout.

The cases in Group B, Table II., were all boys who gave histories of acute rheumatism at some time, but who were clinically quiescent during the period of the investigation. They all showed evidence of organic heart disease.

It seems from these figures that the sedimentation rate is high when there are clinical signs of active rheumatism, and low when the disease is quiescent. The rate is apparently uninfluenced by the degree of cardiac damage that is present.

CONCLUSIONS.

As the result of this investigation we consider that when the clinical picture is that of juvenile rheumatism in an active phase, the blood sedimentation rate is definitely raised; when it is that of quiescent rheumatism or rheumatic heart disease unassociated with clinical signs of activity, the rate approaches normal limits. We feel that further and detailed examination may show that the E.S.R. is of real value in diagnosis of now doubtful cases.

As the result of our clinical experience we have taken as a normal figure, below 10 mm. at the end of the first hour, below 20 at the end of the second hour as the erythrocyte fall as estimated by the Westergren method. In those cases which showed definite clinical signs of active infection the rate varied from 126 to 30 at the end of the first hour, and 136 to 60 at the end of the second hour. In those cases showing no clinical evidence of active infection the reading varied from 9–3 at the end of the first hour, and 20–5 at the end of the second hour.

In a series of cases in which the sedimentation rate was taken at regular intervals during the child's stay in hospital the readings showed that as the active phase subsided the blood sedimentation rate tended to fall.

From these preliminary tests we feel that further investigation should be carried out to determine whether or not the blood sedimentation test should be included with the weight, the temperature, and the pulse-rate in the routine investigation of the rheumatic child. In practice in dealing with rheumatic children we suggest that in a child with a sedimentation rate of 11–21 or over active disease should be suspected in the absence of the usual clinical signs indicative of activity. If there is no clinical evidence of other infection, such as acute rhinitis or sinusitis, the presence of a definitely raised sedimentation rate may be taken as sufficiently suggestive evidence to necessitate the treatment of the case as one of active infection.

In our opinion this test is of value in the consulting room as an aid to the initial differentiation between active and non-active juvenile rheumatism which in practice means the decision as to whether or not the child shall be nursed in bed. It is also of value, if estimated at regular intervals during the course of treatment, in deciding when the active infection has subsided and if the child should be allowed to get up. If the sedimentation rate remains above normal limits special precautions should be taken, and this usually indicates that the child should be kept in bed until the E.S.R. falls. If the E.S.R. is persistently low, there is little danger in allowing the child to resume a normal life.

PEPSIN THERAPY OF GASTRIC AND DUODENAL ULCER.*

By K. Glaessner, M.D.,

PROFESSOR OF INTERNAL MEDICINE IN THE UNIVERSITY OF VIENNA; CONSULTING PHYSICIAN TO THE RAINER HOSPITAL.

The great importance of hydrochloric acid in the genesis of the peptic ulcer, upheld by numerous experimental tests, is also proved by clinical experience—e.g., (1) the site of origin can only be where the gastric hydrochloric acid has access; (2) in a healing, cicatrising ulcer the hydrochloric acid content usually decreases; (3) by removing the pyloric portion of the stomach together with the antrum, we achieve a permanent achylia, thereby preventing a recurrence of the peptic ulcer. Since, therefore, hydrochloric acid is the sine qua non for the genesis of the ulcer, the exciting cause must be sought in some local disposition which may be quite trifling: a small hæmorrhage or an embolus of a small end-vessel of the gastric mucous membrane with necrosis. Such small local sites of irritation may appear as a consequence of the most various injuries: toxins (nicotine), infections (anaphylactic injuries such as have been observed by the Italians[1] after injections of horse serum), nerve lesions (vagus injuries), and local and cerebral arterio-sclerotic changes, which Hart states can bring about such disturbances.

I pointed out these causes as far back as 1912, and later, in 1921 at the Congress of Natural Philosophers in Leipzig, I was able to show that we can succeed in producing artificial ulcers of the skin and of the mucous membranes by injecting gastric hydrochloric acid intracutaneously or intramucously. I produced genuine ulcers in rats, guinea-pigs, and rabbits by this means. After intramucous injection a pustule first appears with clear, then cloudy contents; a necrosis develops and the dead tissue falls off in about ten days, giving place to a roundish ulcer with a flat or deep base and slightly upturned rims, healing with a scar in about four weeks. Such intramucous ulcers take root with far greater difficulty in that portion of the stomach which has covering cells than in the region of the main cells—the central portion, for instance—a sign that cell disposition also plays a part, and that antipepsin is perhaps confined to certain cells. Guinea-pigs are the best subjects for intracutaneous experiment. The experimental skin ulcers, if left to themselves, required four to six weeks for healing, but if a neutral pepsin solution was injected subcutaneously, healing was much more rapid; a fully developed ulcer retrogressed after a fortnight. The chief idea was that the pepsin did not act as a simple irritant but—being the strongest ferment of the human body—was an external, and probably also an internal, hormone of the covering cell gland which we call the stomach.

---

* Read before the Medical Society, Vienna, on June 19th.

The gastric juice of normal persons and of ulcer patients differs biologically. If, for instance, the gastric juice of a normal individual is introduced beneath the skin of a guinea-pig, a slight necrosis will result; this will become a rapidly spreading extensive ulcer if the gastric juice of an ulcer patient is added. The process can be shown still more distinctly on the cornea of experimental animals, in which an erosion painted with ulcer gastric juice takes much longer to heal than an erosion painted with normal gastric juice.

PEPSIN THERAPY.

I have made these facts the basis of a clinical treatment of ulcer and E. Moser,[2] of Zittau, verified my experiments.

This subcutaneous pepsin therapy, which I have now been practising for about five years, entailed much important preliminary work. To begin with, pepsin cannot be sterilised, as a ferment loses its effectiveness at a temperature of above 36°. This was a most difficult problem, the more so as the ferment researchers persisted in maintaining that enzymes do not pass through a filter and that a filtered pepsin solution must be ineffective. This, however, is not the case. Filtering pepsin through porcelain filters under pressure renders the solution free from albumin, but it does not lessen the ferment contents. Thus the pepsin was freed from germs by porcelain filtration; at the same time an antiseptic (diluted carbolic acid) was added to keep the filtered solution free from germs. Absolute neutrality is essential, for the slightest variation will cause local injuries on the skin which render treatment very difficult. Injections of pepsin solutions prepared by my method are harmless and painless. Sometimes, to be sure, larger doses produce certain—probably anaphylactic—phenomena: swelling and reddening of the skin and of the hypodermic cell tissues, slight rises of temperature, and a feeling of fatigue; and occasionally we have observed local exanthemata. But these reactions are exceptional and easily avoided by careful, individual dosage. That the pepsin action is not an albumin action is shown by the facts that the therapeutic effect is lost by boiling and that the filtered solution is free from albumin.

METHODS OF APPLICATION.

I have—after long experience—evolved the following formula. Twice in a year the patient receives a series of 30 injections, increasing and decreasing. The Austria Pharmacy in Vienna† has, for the last two years, put on the market ampoules ready for use. I begin with 0·2 c.cm. and give three injections either daily or every other day; after three injections I increase to 0·3 c.cm.; after three further injections to 0·4 c.cm., after three further injections to 0·5 c.cm. I stop at 0·5 c.cm. for 12 injections, then decrease again to 0·4 c.cm. three times; 0·3 c.cm. three times, and 0·2 c.cm. three times; the series ends at 0·2 c.cm. If anaphylactic symptoms appear, it is wise to use the next lower dose and proceed again; but it is also quite possible to stay consistently at a lower dose without any increase.

Up to date I have treated more than 600 cases, mostly in hospital or ambulatory; ambulatory treatment is quite possible, as the therapy need not interfere with work. Gastric and duodenal ulcers represent the chief material. The new therapy was applied to all ulcers which offered no strictly surgical indication—e.g., stenosis, perforation, severe perigastritis, sudden hæmorrhage under certain conditions, or suspected carcinoma. Œsophageal and jejunal ulcers were also treated. We left gastric hæmorrhages without treatment for three weeks before beginning injections.

I am able now to give a report of about 130 cases which were observed in my ward; we had 23 gastric and 105 duodenal ulcers and two jejunal ulcers. These cases were examined as follows: acid values determined, patient X rayed, weight taken before and after treatment, examination of stools; in many cases neutral red evacuation and test of local sensitiveness to pressure; finally, the subjective feeling (pain, fullness, heart-burn regurgitation of food) was registered. The determination of the acid values, of weight condition, and X ray examination before and after treatment gives a good picture of the great effectiveness of the therapy.

(*a*) In 50 out of 94 thoroughly examined cases the acid values decreased, and in 44 cases they remained stationary or even increased; *this strange* result has nothing to do with the effectiveness of the therapy, save that it shows that the potentiality of ulcers still exists, the danger of a relapse being imminent. In these cases a repetition of the therapy is necessary, for only when th acid values—particularly the value of the fre hydrochloric acid—decrease steadily can the conditio be regarded as cured or clinically latent. It i interesting that in cases of ulcer with low acid value an increase was frequently noticed; it was just thes cases that exhibited a particularly good healing tendency.

(*b*) The weight was accurately examined in 9 cases; eight cases remained constant (8·8 per cent.) six cases showed a decrease of weight which varie between 0·5 and 2·5 kg. (6·2 per cent.); on the othe hand, 80 cases (85 per cent.) showed an increase o weight which amounted to 14 kg. We were als able to achieve increase of weight by the use o pepsin in other cases where weight was lost.

(*c*) It is difficult to explain the changes in th radiographic findings, since changes in the mucou membrane surface are frequently irreparable, even i the ulcer is healed. However, I was able, upon th absolutely objective examination by our radiologis at the hospital—I never undertook this examinatio myself—to establish positive improvement in 72· per cent. This improvement consisted either in th disappearance of sensitiveness to pressure; in norma formation of the duodenal cap; in disappearanc of niches and filling *defects; and in* better evacuatio In 27·6 per cent. the radiogram remained unchanged In a great number of cases the highly important six hour residue had disappeared.

(*d*) The neutral red test was made in a great numbe of cases. Here, also, the prolongation of the time o secretion was an important criterion of improvement In cases where the time of secretion had not decreased the series of injections was repeated. The procedur is very easy: injection of 5 c.cm. of a 1 per cent neutral red solution and examination of the gastri juice of the empty stomach with the duodenal probe Normal individuals evacuate the pigment aft 15 minutes, ulcer patients in a shorter time, cases o hypochlorhydria in a longer time, and achylics not a all (Glaessner and Wittgenstein). About 70 per cent of the cases showed a reduction of the time o evacuation.

(*e*) Occult blood soon disappeared under the treat ment. In 11 cases of very severe hæmorrhage the blood disappeared from the stools.

---

† Vienna, ix., Währingerstrasse, 18.

(*f*) The blood picture before and after the pepsin injections showed a gradual increase of value, even in cases of severe hæmorrhage. I found in general an increase of the eosinophils up to 8–10 per cent., and a leucopenia at the expense of the lymphocytes—I sometimes found 3–5 per cent. of lymphocytes. Perhaps pepsin, like certain albumoses, produces the eosinophilia.

(*g*) The subjective phenomena improve very soon. Disappearance of pain is often observed after six or seven injections. The sensitiveness to pressure diminishes; the feeling of fullness, the repeating of food, the heart-burn, the pain at night and from hunger, the painful sensation of the empty stomach, all relax. The patients are rarely refractory; about 5 per cent., in spite of the cure, still had pain. Only five of our 130 cases went to the surgeon (4 per cent.).

Even if the patient makes no complaint, I am in favour of repeating the treatment twice in the year for two years; relapses occur sometimes. I have seen from 10 to 15 per cent. of relapses which were to be attributed to the fact that the patients were hospital cases belonging to the labouring classes and could not follow my directions. In cases which do not improve promptly we suspect other processes—e.g., cholecystitis, lymphogranuloma, tuberculosis and other affections of the pancreas, and cancer.

(*h*) Besides the injections the following factors are part of my routine: before meals the patients take olive oil, about 50 c.cm. per day (five tablespoonfuls), and after meals a bismuth-preparation; bismuth carbonate, "bismoterran," or bismurated magnesia have proved satisfactory. All belladonna preparations are avoided and other drugs—sodium bicarbonate in particular—are cut out. If there has been no hæmorrhage or inflammation the patients have a mixed diet, the customary milk and fasting cures in particular being avoided. We give them mixed milk and cream and whipped cream. Sugar and honey agree with some patients, but not with all. They can also have eggs, soft cheese, milk dishes, vegetables of all kinds passed through a strainer, mashed potatoes, rice, hashed white meat, fish, and farinaceous food well greased. Soups should be prepared of vegetables or cereals; small quantities of bacon, unsweetened cooked fruit, toasted bread, or zwieback (rusks), and alkaline waters should be given. The quantity of each article of food is about 100 g., but the patient should always feel satisfied; he therefore takes numerous small meals—six a day.

Besides the injection treatment, medicines, and diet, a few physical measures deserve consideration—e.g., lying on the right side after eating, thermophore or mud packing, and daily stools (bismuth preparations).

RESULTS.

It is not easy to state the results of the treatment in figures. In the following table only objective factors are stated.

Cases observed, 130: operated on, 5 (4 per cent.); severe hæmorrhage, 11 (9 per cent.).

Of 94 fully investigated cases—

Acid values ..	Unchanged or higher..	44	(47 per cent.)
	Lower	50	(53 " ")
X ray findings	Unchanged	26	(27·6 " ")
	Improved	68	(72·4 " ")
Weight ..	Unchanged	8	(8·8 " ")
	Reduced	6	(6·2 " ")
	Increased	80	(85 " ")

Besides gastro-duodenal ulcers, jejunal, œsophageal, and other ulcers may also be favourably influenced by pepsin injections. Mucous membrane ulcers of the mouth and pharynx rapidly improve, while ulcers of the lower leg and of decubitus granulate in a surprisingly short time. Similar observations were made by Moser, who achieved complete cures of radiographic ulcers. The ulcers of diabetics and nerve patients retrogress quickly, and we have seen a few most encouraging cases of ulcerative colitis. In pernicious anæmia we have likewise had encouraging results with pepsin injections. Here the pepsin probably acts as a gastric mucous membrane extract, like "ventæmon" or "stomopson."

In 1930 Loeper, Debray, Michaux, and Mlle. Sainton published [4] an article entitled Le traitement de l'ulcus par les injections hypodermiques de "Pepsin" in which, ignorant of my publications as far back as the year 1927, they record a small number of cases in which the cure of gastric or duodenal ulcers was effected by pepsin injections. In the following year (1931) [5] I claimed my priority, which Loeper and his collaborators were obliged to acknowledge. Nevertheless, the article of the French authors is a complete confirmation of my statements and results, and it is pleasant to think that investigators completely independent of each other should arrive at the same satisfactory results.

Recently W. Hertzer published a thesis [6] which treats of experiments carried out at Kuttner's instigation in the Rudolf Virchow Hospital in Berlin; The author records 12 cases in which he tested my method; in all these, save one, he achieved the same results as I, and even more favourable ones. After 20 injections of pepsin all the patients were free from pain and trouble; the increase in weight varied between 2·6 and 6·4 kg.; the acid values were—as in the patients under my observation—somewhat increased in a few cases while in others they changed little or became subnormal; the X ray findings showed a striking improvement and were pathological after the cure in only two cases; the blood disappeared in all cases. No medicine was administered besides the injections, and a normal diet was given. During the treatment no complications occurred, and except in one case no local reactions or fever were ever observed. The treatment was carried out with the pepsin injections prepared by the Austria Pharmacy in this city, according to my directions. This is a splendid proof of the effectiveness of the therapy.

SUMMARY.

Pepsin injection therapy can, in about two-thirds of the cases of uncomplicated duodenal and gastric ulcer, bring about an objective and subjective cure. Of the last 100 cases which were observed, more than half showed an improvement of the acid values, about three-quarters one of the X ray finding, and four-fifths one of the weight curve. Remittent treatment is recommended: in addition, only indifferent medicines and a plentiful diet are prescribed. Only 6 per cent. of the cases had to undergo operation. Other ulcer formations also (mucous membrane, skin, decubitus, intestinal) may be cured by this treatment. It is a specific therapy and depends more on hormonal factors than on the action of irritants.

LOW SPINAL ANÆSTHESIA.

BY J. K. HASLER, M.B. LOND.,
SENIOR ANÆSTHETIST TO ST. MARK'S HOSPITAL; ANÆSTHETIST TO THE DREADNOUGHT HOSPITAL AND TO THE MILLER HOSPITAL.

Low spinal anæsthesia—or to give it its academic title, intrathecal caudal anæsthesia—consists in the injection of a suitable drug into the subarachnoid space so that the resulting anæsthesia is limited to the caudal region. Its use is therefore confined to operations involving the perineum, and it has a wide application in those gynæcological, genito-urinary, and rectal operations which take place in this area. During the past two and a half years I have used this form of anæsthesia in about 600 cases at St. Mark's Hospital and elsewhere. In the majority of these the operation has been for rectal conditions such as hæmorrhoids, fissures, and fistulæ.

TECHNIQUE AND MANAGEMENT.

The technique varies somewhat according to the anæsthetic agent employed. As Howard Jones[1] has said, "The movement of injected solutions is determined by their relative weight." If, therefore, a solution of higher specific gravity than cerebro-spinal fluid is introduced into the spinal canal it will at once tend to sink. This fact can be demonstrated by injecting a solution such as 10 per cent. stovaine in saline into a patient lying on his side. If the patient is allowed to remain on his side after the injection, his lower leg will become anæsthetic and paralysed and the upper one will be unaffected. It follows that for low spinal anæsthesia produced by means of a heavy solution, the patient should adopt the sitting posture during and for a short time after the injection, so that the solution may gravitate downwards and act only on the sacral nerves. If, on the other hand, it is decided to use a solution of lower specific gravity, such as percaine 1 : 1500 or 1 : 1000, the patient should, after injection, be placed prone in the horizontal position or with the head of the table slightly lowered.

In nearly all my cases I have used 10 per cent. stovaine in saline, and am now using it as a routine. Although this has for many years been called the "light" solution it has a specific gravity of 1080 and, besides being heavier than cerebro-spinal fluid (average specific gravity 1007), it is also heavier than the so-called "heavy" solution which contains 5 per cent. stovaine with 5 per cent. glucose in distilled water (specific gravity 1023).

The patient is given a preliminary narcotic injection about three-quarters of an hour before operation. On arriving in the anæsthetic room he is asked to sit up and place his feet on a stool at the side of the table. The skin over the spinal column is prepared by painting with iodine and the patient is asked to bend forwards. An injection of novocain (1 per cent. or 2 per cent.) is given intradermally and subcutaneously over the most convenient lumbar intervertebral space. Although the space between the fourth and fifth lumbar vertebræ is the site for choice it may be difficult to locate, especially if the patient is stout. In these circumstances it is often easier to palpate the spines of the third or the second lumbar vertebræ and to inject in the space below. I have also given the injection between the fifth lumbar vertebra and the sacrum.

The spinal needle is then inserted in the middle line. As soon as it enters the theca, and the cerebro-spinal fluid runs freely, an injection is given of between 0·4 and 0·5 c.cm. of the stovaine solution. The injection is made slowly to avoid unduly mixing the stovaine with cerebro-spinal fluid. After the needle is withdrawn the patient remains sitting for about two minutes. This allows time for the stovaine to gravitate downwards and act only on the lowest sacral nerves. The patient can then be placed on his back and wheeled into the theatre.

By the time the patient has been moved to the operating table, placed into position, and prepared for operation, anæsthesia is usually complete. In most cases five minutes is ample time between the spinal injection and the first incision, though it occasionally takes two or three minutes longer for complete anæsthesia to develop. The patient may be conscious of deep pressure at the start but this rapidly disappears.

If the area of anæsthesia is tested it is found that usually the only nerves to be affected are the third, fourth, and fifth sacral. This means that a saddle-shaped area of anæsthesia is present in the perineum and the patient retains complete sensation in and the full use of his legs. Sometimes the second sacral nerve is affected also and a band of anæsthesia is found at the back of the thigh reaching as far as the popliteal space. There is also anæsthesia of the penis and scrotum, though this may be only partial if the second sacral nerve has remained unaffected. With still higher anæsthesia the foot becomes numb and the patient speaks of tingling in the legs even if full anæsthesia does not occur.

As a general rule, the higher in the lumbar region that the injection is given, the more extensive will be the area of anæsthesia. If the stovaine is introduced between the fifth lumbar vertebra and the sacrum it is highly improbable that any nerves above the third sacral will be affected. If, however, it is given in the second or third lumbar interspace there is usually some anæsthesia and paresis in the legs. Area of anæsthesia will also vary with the dosage. An injection of 0·3 c.cm. of stovaine may limit anæsthesia to a small area round the anus which, while it may permit an operation for hæmorrhoids to be performed, is insufficient for the treatment of a large fistula in ano. An injection of 0·4 c.cm. appears to be the best dose for rectal operations, while for genito-urinary work it is as well to give 0·5 c.cm. to ensure blocking the second sacral nerve. Nor is the area of anæsthesia always symmetrical. It oftens happens that the third sacral nerve is the highest affected on one side and the second is paralysed on the other; or one leg may be partially anæsthetised and the other not at all. In no case, however, has anæsthesia been high enough to operate on an inguinal hernia.

With anæsthesia confined to the sacral region only a small portion of the sympathetic nervous system is involved and consequently there is no drop in blood pressure. The patient need not have his head lowered, and many of my cases have enjoyed the use of two pillows during operation, thus having the level of the head higher than that of the abdomen. There is no pallor nor faintness, nor have any of the patients complained of the nausea and sickness which is commonly found in those who have had the whole abdomen anæsthetised by means of spinal anæsthesia. Any action which the stovaine may have in producing toxic symptoms is completely absent in this form of anæsthesia, and in no case has the patient's condition given cause for concern.

A bandage is usually placed round the patient's eyes before entering the theatre, though many prefer to do without it. In any case there is little to be seen by a patient lying in the lithotomy position. One patient, seen in private practice, was content to read his morning paper while his hæmorrhoids were being removed. Absence of apprehension has been a striking feature of this method.

POST-OPERATIVE CARE.

As there is no drop in blood pressure it is not necessary for the patient to lie with the foot of the bed raised on blocks when taken back to the ward.

Two precautions are taken against the occurrence of post-operative headache. Firstly, the injection of anæsthetic is made with a fairly fine spinal needle (standard wire gauge 20), and the bevel of the needle is made to face laterally while puncturing the dura mater. This is the method advocated by Labat[2] to reduce the size of the puncture hole and thus minimise draining away of cerebro-spinal fluid. Secondly, the patient is, on his return to the ward, encouraged to lie still for the rest of the day and not more than one pillow is allowed.

Post-operative headache has been comparatively rare among these cases, and as far as I have been able to ascertain has not lasted for more than a few hours when present. When it does occur, the patient should be made to lie flat, preferably without a pillow, and aspirin or phenacetin should be given by mouth. It is interesting to note that among 24 cases described by Spencer[3] in the United States only one case of headache is recorded, although the patients were allowed to get up and go home an hour or two after having their operations performed under low spinal anæsthesia. The exception, a man of 26, "left the office at 10.30 P.M. with instructions to go home to bed. He did so, but arose again at 1.30 A.M. and drove a milk wagon for several hours."

Only one other complication has occurred among these cases. I refer to an occasional instance of retention of urine. It is difficult to estimate the part, if any, played by spinal anæsthesia in causing this as it may also occur after perineal operations when the patient has had a general anæsthetic. A useful preventive measure is to encourage the patient to attempt micturition every hour for the first three or four hours after operation.

ALTERNATIVE ANÆSTHETIC AGENTS.

In addition to the 10 per cent. stovaine in saline I have also used the solution composed of 5 per cent. stovaine and 5 per cent. glucose in distilled water. It appears to work equally well and I have usually injected 0·7 c.cm. as the dose. Silverton,[4] in Sydney, employs an even smaller dose of this solution. He found that 2 cg. (0·4 c.cm.) of stovaine was enough to provide anæsthesia for cystoscopy and most perineal operations, and that 3 cg. (0·6 c.cm.) was necessary for litholapaxy and perineal prostatectomy.

I have also used a solution of percaine 1 : 1000 with 5 per cent. glucose added to raise the specific gravity of the solution. An injection of this (2 c.cm.) gives a satisfactory perineal anæsthesia but it does not appear to have any advantages over 10 per cent. stovaine in saline. The anæsthesia takes rather longer to develop. If plain percaine 1 : 1500 is used an injection of 5 or 6 c.cm. is necessary and this again takes a few minutes longer to act than stovaine. It is probable that for low spinal anæsthesia percaine, when used, should be in greater concentration, and Howard Jones[5] advocates the use of 0·5 to 1·0 c.cm. of 1 : 100, or 1 to 2 c.cm. of 1 : 200 solution. This may produce anæsthesia for as long as six to eight hours. The only advantage of such a prolonged action would appear to be in diminishing the need for post-operative sedatives.

In the United States, Pitkin[6] and McCormack have employed low spinal anæsthesia in obstetrics. Finding that the use of spinocain was impracticable they substituted glucose for the alcohol and increased the strength of novocain in the solution from 10 per cent. to 40 per cent. Their heavy solution is on the market under the name of Gravocain and, with such a concentration of novocain, the addition of glucose seems unnecessary to make the solution heavier than cerebro-spinal fluid. Spencer[3] has also used this, chiefly for genito-urinary work. It has been his practice to perform minor perineal operations on patients in his surgery after which they may return home within an hour or two, walking if necessary.

I have not used simple solutions of novocain for low spinal anæsthesia, but it would no doubt prove perfectly satisfactory for those who prefer this drug to stovaine. I have found stovaine so extremely efficient for this form of anæsthesia that I hesitate to make a change.

CONCLUSIONS.

From the foregoing remarks it will be seen that low spinal anæsthesia may be employed with advantage for a large variety of operations. Among these are the following: circumcision, operations for stricture, such as internal urethrotomy and the passage of dilators, cystoscopy when an anæsthetic is required, litholapaxy, diathermy to bladder or prostate, perineal prostatectomy, operations for hæmorrhoids, fissures, and fistulæ, insertion of radium into carcinoma of the rectum, and in the operative treatment of rectal prolapse. Pitkin has also used it in obstetrics and for dilating and curetting the uterus. In the last-mentioned operation he found that dilatation of the cervix was painless but that curettage of the uterine fundus caused some discomfort. It is not suitable for operations on the testicle, as this organ is not supplied by the sacral nerves.

Low spinal has certain definite advantages over other forms of anæsthesia. The nausea and vomiting which occur after a general anæsthetic are absent, nor does the patient require to be watched while the effect of the anæsthetic is passing off. There are no circulatory and respiratory disturbances such as are caused by the administration of a general anæsthetic. If tests for renal function are being carried out by intravenous injection of indigo-carmine, there is no delay in the excretion of the dye such as occurs when the patient is under general anæsthesia.

Lundy[7] and Buie,[8] both of the Mayo Clinic, strongly urge the claims of caudal and trans-sacral blocks for surgery of the perineum. Used by itself caudal block anæsthesia takes longer to develop and, in my experience, causes more discomfort to the patient than a spinal injection. Moreover, the anæsthesia produced is not so profound as with a spinal anæsthetic and a certain percentage of failures is usual. If a trans-sacral block is given also, good anæsthesia results but greater time is required for administration. Nor can the anæsthetist hope to become proficient in the technique of producing a trans-sacral block without considerable practice. Low spinal, on the other hand, is easy to administer, rapid in action, almost painless to the patient if given with care, and provides a profound anæsthesia for the area of operation. There is no drop in blood pressure and the patient's sense of wellbeing is not disturbed as with higher forms of spinal anæsthesia. With careful administration it should be successful in every case, and so far I have seen no case out of 600 where anæsthesia was unsatisfactory and had to be supplemented.

The views of two surgeons who have had considerable experience with this form of anæsthesia may with advantage be quoted here. Milligan,[9] says:

> "Low spinal, or spinal anæsthesia limited to the sacral nerves, has advantages which render it of the greatest value for operations on the perineum. It is reliable . . . It is a controllable anæsthetic and has none of the disadvantages of the higher spinal anæsthetics. . . . The administration of the anæsthetic is simple and is quickly carried out. It is not unpleasant to the patient and is convenient to the operator if he is skilled in the technique. Anæsthesia is complete in two or three minutes. Apprehension before operation can be abolished by suitable injections. For hospital work it is ideal."

Silverton,[4] in New South Wales, says: "This is, as it were, an example of an almost perfect form of regional anæsthesia induced with great rapidity by a very simple technique."

SUMMARY.

1. For operations on the perineum low spinal is a very satisfactory method of producing anæsthesia. 2. It is easy to administer, rapid in action, and provides good anæsthesia limited to the area of operation. 3. There is no drop in blood pressure, and the condition of the patient remains good throughout. 4. These advantages should be applicable to 100 per cent. of cases.

I wish to express my thanks to Mr. W. B. Gabriel and Mr. E. T. C. Milligan for their coöperation in this work, and for kindly offering their criticism of this paper.

ON A DIVERGENCE BETWEEN THE BIOLOGICAL AND GAMMA RAY EFFECTIVENESS OF RADIUM TUBES.

BY S. RUSS, D.SC. LOND., AND G. M. SCOTT.

From the Barnato Joel Laboratories, Middlesex Hospital.)

IN radium therapy use is made of many types of tubes and needles of varying degrees of screening; they are generally made of platinum, but occasionally of other metals, such as silver, lead, brass, or monel metal. Whatever the metal may be, the question often arises—what is the optimum thickness? This does not seem to be an easy question to answer. The object of this note is to draw attention to the fact that platinum radium tubes of the *same* normal gamma ray output will have a varying biological range of effect, which does not simply depend upon the degree of gamma ray absorption by the platinum.

In order to illustrate the point in question reference will be made to tubes of only three thicknesses—2·0 mm., 0·6 mm., and 0·3 mm. of platinum. These tubes were all the same length (2·0 cm.), and their specifications are given in Table I.

It will be seen from this Table that the actual content of the three tubes does not vary much, but there is naturally a marked difference in the gamma ray activity of the three tubes, due to the difference in screening. The tube with walls of 0·3 mm. is 5 per cent. more active than that with walls of 0·6 mm., and the one with 0·6 mm. walls is 18 per cent. more active than that with 2·0 mm. walls. This difference in the gamma ray effectiveness of these tubes would be measured in any physical laboratory where gamma ray measurements are carried out with an electroscope with walls of not less than 3 mm., the thickness calculated to allow only gamma rays to enter.

TABLE I.—*Details of Tubes.*

Tube.	Wall thickness of platinum.	External diameter.	Actual radium content.	Gamma ray activity.
A	2·0 mm.	5·0 mm.	3·00 mg.	2·42 mg.
B	0·6 „	2·2 „	3·08 „	2·87 „
C	0·3 „	1·6 „	3·14 „	3·03 „

It is common knowledge that gamma rays, like X rays, when incident upon material substances cause electrons to be emitted, and the gamma rays passing through the platinum tubes will cause streams of beta rays to issue from the tubes; but the ordinary gamma ray measurements obviously take no account of this. Such beta rays constitute an easily absorbed type of radiation which, although it is not detected by the gamma ray electroscope, will have a marked effect on the tissues within a limited zone around any tube or needle.

Ionisation measurements have been made with tubes of the three different thicknesses of platinum mentioned above to find out how far this easily absorbed radiation would extend into the tissues. An ordinary cubical electroscope (with 10 cm. sides) made of thin aluminium foil (0·18 mm.) was used, so that any ionisation produced by easily absorbed radiation would be measured, as well as that due to the primary gamma rays.

The central axes of the tubes were set vertically 18 cm. from the electroscope, and comparisons made between the actual ionisation measurements obtained and the ordinary gamma ray measurements. The tube with a 2 mm. wall thickness was used as a basis for comparison with the other tubes, and the amount of ionisation registered per mg., after allowing for the absorption by the 2·0 mm. platinum walls of the tube, was decided on as 100 per cent.; similar ionisation measurements of the other tubes were then compared with this. It was found, after the necessary absorption allowances, that the tube with a wall of 0·6 mm. platinum gave 113 per cent. ionisation, and the 0·3 mm. tube 145 per cent. to 165 per cent. The variation in this latter figure was due to the fact that the wall of the 0·3 mm. tube was not

* For all these observations the thinnest side of the tube was kept directly facing the electroscope.

uniform; as this tube was turned round the vertical axis the ionisation figures varied from 145 per cent. o 165 per cent.

As these data showed that if the tubes with walls of 0·3 mm. platinum instead of 2·0 mm. were used biologically, as much as 65 per cent. more radiation might come into play, the lightly screened tubes were coated with paraffin of almost as great a density as the soft tissues of the body, and observations were made to see how much paraffin was needed to obtain he same percentage ionisation effect with these ubes as that given with tubes with walls of 2·0 mm. Table II. shows these ionisation figures.

These observations show that to reduce the percentage ionisation of these tubes to the level of that from the 2·0 mm. platinum tubes, about 1 cm. of paraffin wax (density 0·93) is needed; the equivalent thickness to this in the softer tissues of the body would be about 9 mm. This contributory radiation of easily absorbed type gives these tubes a biological effectiveness quite apart from the smaller absorption of the primary gamma rays that is entailed.

Recently Sven Benner [1] and Piccard and E. Stahel [2] have shown that there are significant differences in the degree to which beta rays are emitted from different metals under gamma irradiation. It may be that some of the excessive reactions that have been noted when lightly filtered tubes have been used can be explained to some extent on these lines. This does not mean to imply that differential action may not also be looked upon as an explanatory factor.

CLINICAL AND LABORATORY NOTES

A SOURCE OF ERROR IN MEASUREMENTS OF URINE SECRETION,

INCLUDING RENAL EFFICIENCY TESTS.

By Phyllis M. Tookey Kerridge, M.Sc., Ph.D. Lond.,

and

Arthur Ellis, M.D. Toronto, F.R.C.P. Lond.,

DIRECTOR OF THE MEDICAL UNIT, LONDON HOSPITAL; PROFESSOR OF MEDICINE IN THE UNIVERSITY OF LONDON.

In many of the tests of renal function used in medical practice, failure to empty the bladder completely will lead to gross discrepancies. While this danger is well recognised, it is commonly regarded as an unusual complication, and as associated only with recognisable causes of obstruction. In studying records of urinary secretion, in which each specimen passed over long periods of time was measured, we have found figures which suggest that incomplete emptying of the bladder is not uncommon and that it occurs in the absence of any obvious cause of obstruction. It has therefore seemed worth while to publish these observations so that an appreciation of the importance of this factor as a source of error in such determinations may be more generally recognised.

Some patients with nephritis were observed to pass 150–350 c.cm. of urine within an hour of having previously passed urine. This second specimen was not dilute, but had approximately the same specific gravity and chloride, creatinine and protein concentrations as specimens passed before and after. This behaviour was noticed in four out of 16 cases in which records were kept of each specimen of urine passed over a period of several weeks. *In one patient*, this happened 24 times in 13 weeks; in the others more rarely. There was *no* reason to suspect retention of urine in any of these patients, and it did not occur to us at first that such was the probable explanation of the phenomenon. We regarded it as a sudden and temporary increase in the rate of urine secretion. Diuresis without dilution is unusual, and we therefore tried to reproduce it in these patients by various means—*e.g.*, by *giving* them strong tea; urea by mouth, both in small and in large doses; 100 mg. ephedrine hydrochloride orally; 1 mg. histamine subcutaneously. Our efforts were entirely unsuccessful. Subsequently exactly similar occurrences were observed twice in a patient who was found to have a urethral stricture. It was also recorded twice in a patient with no evidence of any renal lesion; a man with a gastric ulcer who was on a very fluid alkaline diet and who passed about 2500 c.cm. of urine a day. It therefore appeared that the probable explanation of all the cases was a failure to empty the bladder completely on one occasion, causing urine to be voided again after a smaller interval of time than customary. The prone position in which micturition takes place in bed may well be the sole reason for the incompleteness of the act, of which the patient is quite unconscious. No sex difference was apparent from our records. We consider that incomplete emptying of the bladder affords a rational explanation of the large difference frequently seen in renal efficiency tests done at short intervals on patients who are in a stationary clinical condition. This is the more likely since in renal efficiency tests the collection of small specimens is carried out at small intervals of time.

A RECORD OF AN ATTACK OF MANIA.

By L. C. Bruce, *M.C.*, M.D., F.R.C.P. Edin.,

MEDICAL SUPERINTENDENT, PERTH DISTRICT ASYLUM, MURTHLY.

The following case of acute mania (manic-depressive insanity) is interesting, first, because one rarely has the opportunity of seeing such an attack from the onset to the recovery, with a complete blood chart, and secondly, because it is still rarer to isolate an organism from the blood, which in this case gave a positive skin reaction.

The *patient*, a man of 40, had previously been in this hospital, suffering from an attack of melancholia with suicidal tendencies, from which he made a good recovery and had been discharged six months ago. He felt ill, and fearing another mental attack he placed himself voluntarily under care and was admitted on March 4th. On admission he looked flushed and anxious and he complained of mental confusion and an inability to sleep. Beyond a pulse-rate of 100 per minute and slightly exaggerated tendon reflexes he presented no marked physical symptoms.

March 5th: He slept very little last night and to-day was confused and constantly talking. 6th: *Did* not sleep at all last night and to-day was very excited and in a condition of delirium with vivid hallucinations of sight and hearing. 7th: Slept for two hours under the influence of paraldehyde. The delirium and the hallucinations continued.

The views of two surgeons who have had considerable experience with this form of anæsthesia may with advantage be quoted here. Milligan,[9] says:

> "Low spinal, or spinal anæsthesia limited to the sacral nerves, has advantages which render it of the greatest value for operations on the perineum. It is reliable . . . It is a controllable anæsthetic and has none of the disadvantages of the higher spinal anæsthetics. . . . The administration of the anæsthetic is simple and is quickly carried out. It is not unpleasant to the patient and is convenient to the operator if he is skilled in the technique. Anæsthesia is complete in two or three minutes. Apprehension before operation can be abolished by suitable injections. For hospital work it is ideal."

Silverton,[4] in New South Wales, says: "This is, as it were, an example of an almost perfect form of regional anæsthesia induced with great rapidity by a very simple technique."

SUMMARY.

1. For operations on the perineum low spinal is a very satisfactory method of producing anæsthesia. 2. It is easy to administer, rapid in action, and provides good anæsthesia limited to the area of operation. 3. There is no drop in blood pressure, and the condition of the patient remains good throughout. 4. These advantages should be applicable to 100 per cent. of cases.

I wish to express my thanks to Mr. W. B. Gabriel and Mr. E. T. C. Milligan for their coöperation in this work, and for kindly offering their criticism of this paper.

ON A DIVERGENCE BETWEEN THE BIOLOGICAL AND GAMMA RAY EFFECTIVENESS OF RADIUM TUBES.

BY S. RUSS, D.SC. LOND., AND G. M. SCOTT.

From the Barnato Joel Laboratories, Middlesex Hospital.)

IN radium therapy use is made of many types of tubes and needles of varying degrees of screening; they are generally made of platinum, but occasionally of other metals, such as silver, lead, brass, or monel metal. Whatever the metal may be, the question often arises—what is the optimum thickness? This does not seem to be an easy question to answer. The object of this note is to draw attention to the fact that platinum radium tubes of the *same* normal gamma ray output will have a varying biological range of effect, which does not simply depend upon the degree of gamma ray absorption by the platinum.

In order to illustrate the point in question reference will be made to tubes of only three thicknesses—2·0 mm., 0·6 mm., and 0·3 mm. of platinum. These tubes were all the same length (2·0 cm.), and their specifications are given in Table I.

It will be seen from this Table that the actual content of the three tubes does not vary much, but there is naturally a marked difference in the gamma ray activity of the three tubes, due to the difference in screening. The tube with walls of 0·3 mm. is 5 per cent. more active than that with walls of 0·6 mm., and the one with 0·6 mm. walls is 18 per cent. more active than that with 2·0 mm. walls. This difference in the gamma ray effectiveness of these tubes would be measured in any physical laboratory where gamma ray measurements are carried out with an electroscope with walls of not less than 3 mm., the thickness calculated to allow only gamma rays to enter.

TABLE I.—*Details of Tubes.*

Tube.	Wall thickness of platinum.	External diameter.	Actual radium content.	Gamma ray activity.
A	2·0 mm.	5·0 mm.	3·00 mg.	2·42 mg.
B .	0·6 „	2·2 „	3·08 „	2 87 „
C	0·3 „	1·6 „	3·14 „	3 03 „

It is common knowledge that gamma rays, like X rays, when incident upon material substances cause electrons to be emitted, and the gamma rays passing through the platinum tubes will cause streams of beta rays to issue from the tubes; but the ordinary gamma ray measurements obviously take no account of this. Such beta rays constitute an easily absorbed type of radiation which, although it is not detected by the gamma ray electroscope, will have a marked effect on the tissues within a limited zone around any tube or needle.

Ionisation measurements have been made with tubes of the three different thicknesses of platinum mentioned above to find out how far this easily absorbed radiation would extend into the tissues. An ordinary cubical electroscope (with 10 cm. sides) made of thin aluminium foil (0·18 mm.) was used, so that any ionisation produced by easily absorbed radiation would be measured, as well as that due to the primary gamma rays.

The central axes of the tubes were set vertically 18 cm. from the electroscope, and comparisons made between the actual ionisation measurements obtained and the ordinary gamma ray measurements. The tube with a 2 mm. wall thickness was used as a basis for comparison with the other tubes, and the amount of ionisation registered per mg., after allowing for the absorption by the 2·0 mm. platinum walls of the tube, was decided on as 100 per cent.; similar ionisation measurements of the other tubes were then compared with this. It was found, after the necessary absorption allowances, that the tube with a wall of 0·6 mm. platinum gave 113 per cent. ionisation, and the 0·3 mm. tube 145 per cent. to 165 per cent. The variation in this latter figure was due to the fact that the wall of the 0·3 mm. tube was not

* For all these observations the thinnest side of the tube was kept directly facing the electroscope.

N. Hobhouse[2] has mentioned a case in which a boy of 11 became left-handed as the result of right hemichorea, and developed a stammer.

In the history of No. 4, the two varieties of transition are exhibited consecutively, in a right-handed member of a family with strong left-handed tendencies. The question as to why the first was *not*, and the second *was* followed by stammer is a difficult one, and suggests various possibilities. It might be submitted that the change to left-handedness was facilitated by its coincidence with a latent hereditary tendency, or that the development of the stammer was conditioned to some extent by the emotional resistance which he experienced towards the return to right-handedness. On the other hand the sequence might perhaps be explained by the relative plasticity of the physiological centres at the time when the first transition was achieved.

MEDICAL SOCIETIES

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

THE last meeting of this society was held at Liverpool when cases and specimens were shown.

Prof. LEITH MURRAY showed a specimen of *Endometrioma of the Anterior Vaginal Wall.*

The patient was 43 years of age and had had one confinement followed by "septic poisoning," since when contraceptive measures had been adopted. Her only complaint was of excruciating spasmodic pain lasting all through the periods. On examination a flat plaque was found on the anterior vaginal wall occupying more than half its surface and stretching up to the cervix. This area was covered with retention cysts filled with blood. Cystoscopy revealed an inward bulge but no involvement of the mucosa. Removal was accomplished partly with scissors and partly by blunt dissection and unfortunately the bladder was opened. Though the opening was closed a fistula developed. There has been no recurrence of the growth and there has been a complete cessation of the dysmenorrhœa. Section showed the tissue to be a typical endometrioma.

Section through one of the linear pits on the surface, said Prof Murray, showed that the squamous epithelium disappeared at the edge. He considered this a possible implantation area.

Mr. N. L. EDWARDS (Derby) showed an *Endometrioma in an Abdominal Scar* following Cæsarean section.

The patient, aged 33. had had a Cæsarean section in 1923. In November, 1929, Mr. Edwards again delivered her by the same route through a left paramedian incision. A section of each tube was resected, the stumps were buried, and the right ovary, which was cystic, was removed. The scar discharged serum from the eleventh to the thirteenth day. Recovery was afebrile. Seen ten months later the patient said that she had noticed a blackish discharge from the upper end of the scar and that during the last seven periods there had been no pain. A small purplish nodule was found at the point of the discharge with the uterus adherent to the anterior abdominal wall behind it. This condition was confirmed when the nodule was excised two months later. At the same time the abdomen was opened and the uterus was removed by subtotal hysterectomy along with the remaining ovary which was now cystic and adherent.

The nodule showed endometrial tissue but no connexion could be found between the endometrium of the nodule and the uterus. Mr. Edwards thought that of the two probable theories of origin—implantation during operation and metaplasia of peritoneal endothelium—the second was the more likely in this case.

Prof. MURRAY described a *Dermoid Cyst of the Left Ovary* weighing over 29 lb., containing fatty balls and pellets.

The patient was a virgo intacta, aged 52, who had passed the menopause five years previously. She had been aware of the tumour for 15 years and at the time of operation the abdomen measured 73 inches at the level of the umbilicus. A 3-inch incision was made in the abdomen and adhesions to the anterior abdominal wall were swept away with the hand. Attempts at tapping having failed the cyst was incised and 5½ pints of greenish fluid containing several thousand fatty pellets was evacuated. These varied in size from a split pea to an almond, but seven were found almost completely rounded and much larger. The rest of the contents, consisting of a fatty pultaceous material, was expressed through the incision, the whole cyst being finally removed. The inner and outer surfaces of the cyst wall were smooth and the only suggestion of a germinal node was a linear thickening about 5 inches long. Examination showed this to be a channel lined by several layers of transitional epithelium with some suggestion of goblet cells. There was also a narrow layer of involuntary muscle-fibre. The sebaceous glands discovered were mainly situated round this area, as was also a hair follicle. Radiographic examination was negative. Some fine hairs were found in the fluid and in some of the balls examined. An examination of the fatty material showed a large proportion of free fatty acid and non-saponifiable matter which explained the fact that the fat was solid at body temperature.

Dermoids of this type, said Prof. Murray, were extremely rare and he thought that by its size this specimen was probably unique.

Miss RUTH NICHOLSON showed an *Unusual Tumour obstructing Labour.*

This was removed seven months after the patient had been delivered by Cæsarean section. Previous to this she had had four normal labours. On this occasion she was seen after she had been in labour for 28 hours with good pains. The head was still high and a mass was felt in the pelvis to the right obstructing delivery. A lower segment Cæsarean section was performed by Mrs. Dobbin Crawford during which the tumour was seen to be separate from the uterus, lying on the right side of the pelvis and retroperitoneal about the size of a kidney. The child's head showed marked moulding and a large caput. At the second operation the tumour was found to lie between the layers of the right broad ligament and shelled out easily. It had no connexion with the uterus. It now measured 3 by 2 by 1½ inches and microscopically proved to be a fibromyoma with a preponderance of muscle elements.

Mr. ST. GEORGE WILSON described a case of *Chancre of the Cervix.*

The patient, aged 48, a multipara, complained of smarting and irritation of the vulva with a copious, and occasionally blood-stained, offensive discharge of two months' duration. The cervix was enlarged and soft and bled on palpation. A diagnosis of carcinoma of the cervix was made and a piece of the growth removed for examination, after which radium was applied. Section showed lymphocytic infiltration and the Wassermann reaction was then found to be strongly positive.

Mr. Wilson said that the idea that chancres in this position were rare, which he had previously held in common with the older writers, had been proved erroneous by Anwyl Davies, of St. Thomas's Hospital venereal diseases clinic. He had shown that the cervix was the commonest site.

Dr. P. MALPAS gave a demonstration of the efficacy of gauze packing in the *Maintenance of Radium Containers in situ.* He showed a series of radiograms taken in each case, 4 and 22 hours after insertion of the radium. They showed no alteration of position. The variety in the distribution of the containers in different cases according to the shape and extent of the growth was illustrated, and Dr. Malpas suggested that a large number of different appliances would be required to meet every case.

Blood culture.—35 c.cm. of blood were taken from the median basilic vein and distributed between four flasks of nutrient broth.

March 8th: Still labouring under delirium, but he had several short lucid intervals. 9th: He had four hours natural sleep last night, but even when sleeping he constantly talked just as if he was in a condition of mania in his sleep. 10th: A very definite mental improvement. 11th: Steady mental improvement. 12th: Now sleeping well and mentally clear but exhausted and easily tired. 16th: Practically recovered.

He went home on March 18th.

Bacteriological findings.—A very spare growth of short streptococci was found in each of the four flasks. The growth was pure in flasks Nos. 2, 3, and 4. The first flask was contaminated with staphylococcus. No subcultures could be obtained from the streptococci.

A vaccine made by adding 5 c.cm. of the contents of flask No. 2, mixed with an equal quantity of a 0·5 per cent. carbolic acid solution in normal saline was used as a vaccine to test the skin reactions. The patient gave a very strong positive. The controls were as follows: all volunteers, one from the hospital staff, were negative. Five cases of manic-depressive insanity in the condition of depression were all negative. One case of manic-depressive insanity, chronic, but at that time passing through a mild maniacal attack, gave a slight positive. Two cases of long standing manic-depressive insanity in a condition of remission: one gave a negative and the other a very faint positive. Two cases of encephalitis lethargica, two cases of dementia præcox, and one of delusional insanity, all were negative.

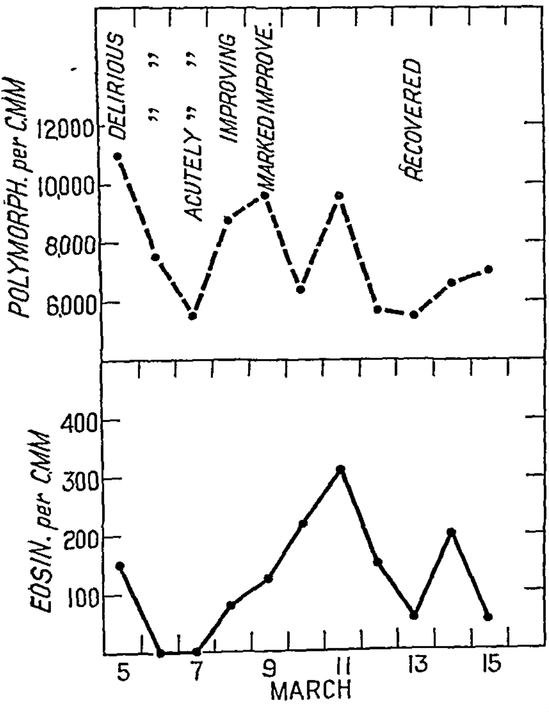

Chart showing variations in the polymorph and eosinophil leucocyte count in relation to the patient's clinical condition.

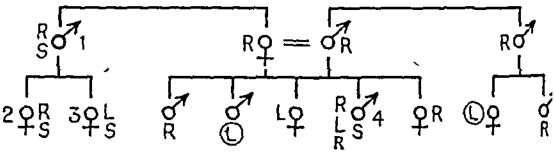
The accompanying chart shows a fall of the polymorphonuclear leucocytes at the period of acute delirium, and a rise on recovery. The eosinophil leucocytes, it will be noted, disappeared altogether from the blood count during the period of acute delirium, reappeared again as improvement commenced, and increased as recovery became complete.

AN UNUSUAL COMBINATION OF LEFT-HANDEDNESS AND STAMMER.

BY LOIS MUNRO, M.B. LOND.,
LATE CLINICAL ASSISTANT, WEST END HOSPITAL FOR NERVOUS DISEASE.

THE following family history seems worth recordin because, while it exemplifies the well-known relatio between left-handedness and stammer, it also contain features which are decidedly unusual.

Four living members of the family stammer No. 1 (see Chart) states that he has stammered sinc he began to speak; he has been right-handed all hi life and remembers no left-handed tendencies. Nos. and 3 are his only children (both daughters); of thes No. 2 resembles her father in each particular, and No. has always stammered but has been left-hande since infancy.



R = right-handed; L = left-handed; L in circle = left-handed tendencies; S = stammer.

A sister of No. 1 (deceased) was normal in speec and was right-handed, as is her husband. A niece c the latter states that she has an inclination to us the left hand, which she overcomes voluntarily; sh also draws from right to left. Of the five childre of the normal pair referred to the first and fifth ar normal in all respects. The second has slight lef handed tendencies. The third is left-handed an normal in speech. In the fourth (No. 4) the sequenc of events was peculiar and raises points of considerabl interest.

The family circumstances were such that No. during his first seven years was looked after almos entirely by his sister, although she was only a fe years older than he. She was firmly convinced tha her own left-handedness was normal, and admit that she regarded her young brother's right-handednes as reprehensible. Accordingly under her influenc the function of writing was firmly established in th left hand by the time when he went to school, at th age of seven. There his mancinism met with uncom promising opposition on the part of the schoo authorities, and within a short time he had acquire the habit of writing with his right hand during schoo hours. During the same period he continued to us the left hand when at home, and at the end of a yea of this régime he had developed a severe stamme It appears that he submitted without resistance t the change from right to left, but strongly resente the return to right-handedness. Now, at the age c 17, he writes with his right hand, but uses his lef hand for other purposes. The stammer has persisted

The causal relationship between thwarted left handedness and stammer has been well recognise since the appearance of W. S. Inman's paper.[1] Th question as to whether stammer may also be occasione by diversion from the right to the left hand has no been established so conclusively, since the oppor tunity of observing this sequence rarely occurs Inman referred to one case in which stamme originated in this way, and to Hugh Gordon's serie of epileptic children at Lingfield Colony schools of course, acted upon by the ovarian substances; this fact is sometimes lost sight of when the actions of these hormones are considered clinically. The growth-producing hormone of Evans is often looked on as associated with, if not similar to the prolans secreted by the anterior pituitary. Prof. Zondek concludes that they are not only distinct but have even some sort of small antagonism in their times of action. His statement that the pituitary hormones of man and beasts are not identical with the corresponding secretions of birds and cold-blooded animals has great biological interest in its indirect bearing on many contradictory experiments on lower forms. The well-known Aschheim-Zondek test for pregnancy is dealt with fully, and some unpublished results are brought forward. The clinical applications and indications of the subjects are discussed, and their association with various cysts and growths of the genital tract are described.

---

[1] THE LANCET, 1924, ii., 211.

This book should be studied alike by clinicians, pathologists, and physiologists.

The Mind in Action.

By A. CAMPBELL GARNETT, M.A., Litt.D., Professor of Philosophy in Butler University, Indianapolis, U.S.A. Contemporary Library of Philosophy. London: Cambridge University Press. 1931. *Pp. 226. 5s.*

Dr. Garnett deals with his subject from the point of view of motive and value, and admittedly derives his psychological standpoint from James Ward and William MacDougall. He is particularly indebted to MacDougall for the latter's Theory of Instinct and Emotion which, however, he does not adopt uncritically or entirely. As regards intelligence in its relation to motive, he is substantially with Prof. Spearman in his acceptance of the general factor. The main burden of the book is to establish the relationship of fundamental motives with sentiments and the growth of the moral self, and the author's view of beauty and truth is that they are the results of a type of harmony which the fundamental processes of mind impose. This is an attractively written book with a bent towards the introspective rather than the experimental method in psychology.

Accidental Injuries.

By HENRY H. KESSLER, A.B., M.D., F.A.C.S., F.A.P.H.A., Medical Director, New Jersey Rehabilitation Clinic. London: Henry Kimpton. 1931. Pp. 71 45*s*.

UNFORTUNATELY medical evidence in a court of law has not always the quality of detachment, but is partisan in nature. This regrettable fact is due amongst other causes to the absence of standards by which the medical witness may assess any given disability, and to ignorance of the prognosis of injuries and diseases. Where such defects of knowledge exist, bias can hardly be avoided. Much useful information to guide the practitioner who is called upon to give evidence in a court of law is provided in Dr. Kessler's book, which will also help him in his examination of the patient. The material collected within its covers is gleaned partly from the study of upwards of 63,000 cases coming before the New Jersey Compensation Bureau, and partly from a comprehensive search of the literature dealing with this aspect of disease. The early chapters treat of the general pathology of injuries, the bad results which may follow them, and the principles on which disabilities can be assessed. Separate chapters are then devoted to the different regions of the body. Traumatic neuroses and occupational diseases have sections to themselves, the latter including industrial poisoning. The last chapter supplies a most interesting account of the rehabilitation of the physically handicapped.

This book will help all who may be called upon to give evidence in connexion with injuries.

Lehrbuch der Röntgenstereoskopie.

By Dr. MAX COHN, Medical Director of the X Ray Department of the Friedrichshain Hospital, Berlin; and Dr. WALTHER BARTH, Physicist to the Agfa Company. Leipzig: Georg. Thieme. 1931. Fully illustrated. Pp. 324. M.30; M.35 bound.

IN 1867 Helmholz published the work which laid the foundation of physiological optics, and so it is not surprising that the majority of the 300 authors mentioned in the bibliography attached to this textbook of X ray stereoscopy are German. The theoretical and practical sides of X ray stereoscopy are fully dealt with, and an accompanying atlas of 26 reproductions of X ray photographs is excellent.

The authors deal seriatim with the difficulties that arise in the application of stereoscopy to X ray work and lead their readers step by step through the increasingly difficult geometrical conception involved. Deploring the scarcity of works on the technique of stereoscopy, the earlier workers having confined their attention to the morbid conditions, they find that the introduction of the mechanical tube and cassette movement has opened up new fields. Their astonishment is frank that there should remain prominent medical men antagonistic to the use of the stereoscope; an astronomer, skilled in the use of the stereo-micrometer for the measurement of the mountains in the moon, might similarly find it hard to believe that there should exist people so unprogressive as to contemplate that orb as it appears to the naked eye, but time has to elapse before new scientific methods become of general use, and they may be reminded that the general adoption of the ophthalmoscope did not occur until 30 years after its description by Babbage.

The introduction by Dr. Max Cohn deals with the value of the stereoscope as a means of research, instruction, and clinical diagnosis, and the same author is responsible for the atlas which is issued with a collapsible stereoscope of suitable size. The remainder of the work is divided into two parts. Part I. by Dr. Barth and Part II. by Dr. Cohn. Part I. contains five chapters on theory grouped under headings such as Subjective and Objective Stereoscopy, and Radiostereometry. In Part II. the author deals firstly with the historical and technical development of stereoscopic photography, and then with the application of these methods in diagnosis, and the relative and absolute indications in surgery and internal medicine for their employment. He deals with the localisation of foreign bodies and follows with a description of corporeal representation of the skin in the X ray picture. A section deals with the extremities, another with the skull including fractures, cerebral tumours, foreign bodies, with paragraphs on the ear, the jaws, and the orbit, and a third with the pelvis and vertebral column, the thorax, the abdominal organs and obstetrics generally. The text is illustrated by two plates, 193 diagrams, and reproductions of photography and skiagraphs. Plate I. gives a stereoscopic diagram and a stereoscopic X ray photograph with movable images and indications of the correct, and four possible incorrect, positions of the image, so that the reader may observe

REVIEWS AND NOTICES OF BOOKS

Chemical Embryology.

By JOSEPH NEEDHAM, M.A., Ph.D., University Demonstrator in Biochemistry, and Fellow of Gonville and Caius College, Cambridge. London: Cambridge University Press. Three volumes. 1931. Pp. 2021. £5 5s.

THERE are over 2000 pages in these three volumes, and a rough idea of the scope may be gathered from the fact that the bibliography begins on p. 1727 and ends on p. 1968. An erudite work of exceptional merit, it is presented in classical style; a portrait of Harvey appears on the page facing the title page, and there follow a Latin dedication and two quotations, one from William Harvey's "Anatomical Exercitations," and the other from one of the works of Joseph Glanville. After the prolegomena the author opens with Part I., entitled The Theory of Chemical Embryology. This is composed of some 30 odd pages dealing with the general philosophic consideration of generation and embryology. Dr. Needham develops his theme in a skilful manner, reviewing briefly the views of the older philosophers who meditated on these problems. His survey concludes with a significant quotation from S. T. Coleridge: "The history of a man for the nine months preceding his birth would probably be far more interesting and contain events of far greater moment than all the three score and ten years which follow it." This doctrine may have inspired Dr. Needham in sacrificing so much intense labour to the production of his great work.

Throughout the first section the author indicates that he is not satisfied with the purely histological and morphological methods of approach, and this attitude is progressively shown in Part II., which is entitled The Origins of Chemical Embryology. From the general reader's point of view this section of the book is undoubtedly one of the most interesting. The description of early Egyptian incubators for hens' eggs reveals many curious methods for maintaining a constant temperature. Dr. Needham takes us through various periods in the world's history, gives references to the Hellenic outlook on embryological problems, traces embryology through the Roman period to Galen, and, not content with the more classical sources of information, he proceeds to a careful review of the Arabian and Jewish literature of very early times. The references to the work of Leonardo de Vinci are illuminating. The facsimile of a page of one of the famous "notebooks" dealing with embryology is curious; the accuracy of Leonardo's observations on this problem is remarkable. As Dr. Needham says "here Leonardo touches on one of the most modern quantitative aspects of embryology, and one almost expects him to exemplify his words with a graph until one remembers with a shock that he lived two centuries before Descartes and five before Minot." The section concludes with an admirable summary of the development of embryological science from the seventeenth century to the present day. Dr. Needham's admiration for Harvey has betrayed him into devoting so much space to extracts from his works that his references to other observers have been disproportionately curtailed. The exposition in greater detail of the views on embryology of Sir Thomas Browne and of Descartes, for instance, would have been welcome.

With Part III. the actual chemical work begins. This and the subsequent matter provide a complete and scholarly account of the biochemistry and physiology of developing eggs. The author has a sharp critical faculty and thus the book is no mere catalogue of facts, but a readable and helpful guide by a leader who knows the way. It may be recalled that it was in connexion with inosite that Dr. Needham's name first became known in the biochemical world; it is thus interesting to read a statement from him on the metabolism of this substance and its derivatives. In the section on carbohydrate metabolism the bibliography is of special value and Dr. Needham deals fully with the application of the modern methods, such as those of Otto Warburg, in the study of this problem. We would have welcomed a fuller description of the author's views on the part played by hormones in the developing embryo. The summary given indicates the great importance of this subject, but in certain places he has been too kind to some of the authors to whose work he refers. In subsequent editions this section will doubtless be extended, a remark which applies also to the section on pigments in the course of development.

This is a great work and should be bought by every institution which can afford to buy it, since it is only by this practical form of encouragement that such a book can be kept alive in new editions. The value of the production from every point of view is so high that it should find a place in every biochemical or physiological library.

Die Hormone des Ovariums

und d. Hypophysenvorderlappens. By Dr. BERNHARD ZONDEK, A.O. Professor in the University of Berlin. Berlin: Julius Springer. 1931. Pp. 343. R.M.40.

WITHIN the last ten or twelve years the anterior lobe of the pituitary has assumed a more definite and forceful rôle in human biology than before. This part had been known for a considerable time as having marked influence on growth, and certainly had been used by clinicians in tentative and empirical ways, but in 1923 definite experimental evidence of a "growth-producing hormone" derived from the anterior lobe was brought forward by H. M. Evans. Aschheim and Zondek, some five years ago, widened the field of action by demonstrating the production by the hypophysis of hormones which did not act appreciably by themselves, but through their effect on other hormone-producing organs. In these researches on the biology and clinical conditions of the female genital functions, Prof. B. Zondek brings together the principal investigations on the subject, including some unpublished work. He has been studying these hormonal actions since 1913, and this contribution to the literature is authoritative. The intricate subject is handled in a simple way. There are no sterile protocols or calculations to exhaust the attention; the results attained are shown shortly and their import explained.

The author opens with discussion of the methods of investigation, and gives details of operative and experimental processes, including the examination of changes in vaginal smears. He passes step by step through the maze of effects of ovarian hormone, as seen in castrated and infantile animals, to the greater intricacies of the action of the hypophysial secretions. The quantitative nature of these seems evident. The absence of pituitary action in castrated animals is clearly shown, though these animals are,

The Therapeutic value of BRANDY—

its lifting and sustaining powers—as compared with other spirits depends on the presence or absence of the higher Alcohols or Ethers. These in turn depend on Grape, Soil, Stills employed, Climate, Storage, Selection and Experience.

It is quite easy to make a spirit from grape wine—It is neither easy nor cheap to make a Brandy containing the qualities you want.

Cognac Brandy alone provides them.

Take no risks;
ensure the results you expect

Prescribe Brandy distilled in Pot Stills from Wines grown in the best Cognac districts; Matured in warehouses which have been filled with Cognac Brandy for centuries; Made by Men with the inherited Experience of Seven Generations.

In short—Prescribe
MARTELL'S BRANDY

for himself the results of error. Plate II. illustrates the localisation of a foreign body. A table of data, determined by experiment, gives the limits of accuracy of accommodation and convergence over various distances.

The book is easy to follow, for the authors have spared no pains to illustrate their points in logical sequence, in order, as they say, to convince the sceptic. It is doubtful, however, whether X ray stereoscopy can be generally adopted, even with this work at the disposal of the radiologist.

Of the value of the technique in the hands of such experts as the authors there can be no doubt. It is the unlucky fact that at the present moment the book costs in English money 48*s.* 6*d.*

A Text-book of Physical Education.

By JESSE FEIRING WILLIAMS, M.D., Professor of Physical Education, Teachers' College, Columbia University; and WHITELAW REID MORRISON, M.D., Professor of Hygiene and Physical Education and Director of the Men's Gymnasium, Oberlin College. London: W. B. Saunders Co., Ltd. 1931. Pp. 343. 12*s.* 6*d.*

THE authors of this book in their preface lament the fact that the facilities for physically educating boys and girls are far removed from the comprehensive measures embodied in technical and academic education. Such a plaint from American professors of physical education sounds strange to us, in view of the contrast between the elaborate systems known to exist on the other side of the Atlantic with the casual haphazard procedure with which we are familiar in this country. It is of course arguable that undue emphasis is placed upon the need for study of what is only a subordinate feature in school and university life; and it must be a matter of opinion to what extent it is desirable to attempt an intellectual campaign on this subject among the students themselves, as the authors hold to be desirable. In this country we think rather in terms of the therapeutic and corrective, and regard these as the province of the medical profession. In numerous quarters the part played by recreation and competitive athletics in our schools and colleges is already considered to be rather too great, and a policy which insists upon exercise as a systematic part of the curriculum would meet with severe criticism. On the other hand, a higher degree of physical, mental, and social fitness might arise if young people were made to take an intelligent interest in the physical activities that play so large a part in their lives, and it is at least a plausible argument that attention should be paid in the selection of the most suitable form of exercise having regard to the future career of the student—whether a sedentary, professional, or commercial life or a physically active career is in prospect. To all those with views on this subject this readable book should make an appeal.

After a historical introduction the authors proceed to enunciate anatomical and physiological principles in some detail, yet in language intelligible to the layman. These sections are followed by a discussion on strenuous exercise, with advice on training along common-sense lines. A chapter on injuries and minor ailments is unexceptionable though the enthusiastic insistence upon the possibility of overcoming certain physical defects by set exercises is perhaps too optimistic. An address on Longevity by Sir Farquhar Buzzard is quoted in approval of the rôle of "the understanding spectator" unable himself to participate in violent muscular exertion, and a chapter on "How to Read the Sport Page" is appended to educate the ignorant and inexperienced in the essentials, the technical details, and some of the jargon of the sporting journalist.

This book can be recommended as an authoritative and comprehensive manual on the subject. It is illustrated with action photographs which admirably fulfil the function proper to such illustrations.

Infant Feeding in General Practice.

By J. C. V. BRAITHWAITE, M.D., M.R.C.P., Physician in charge of Children Out-patients, Leicester Royal Infirmary and Children's Hospital. Bristol: John Wright and Sons, Ltd. Pp. 140. 4*s.* 6*d.*

THIS book is written by a general practitioner who is brought into close contact with problems of the home and of the management of parents. The chapter on the routine of breast-feeding and its difficulties contains much valuable practical advice. For artificial feeding Dr. Braithwaite recommends simple dilutions with added carbohydrate as the method of choice, and gives a clear account of the indications for varying this method. The latter part of the book deals with nutritional disorders of infancy, and contains an intelligible summary of the essentials of the theories of Czerny and Finkelstein. This book is thoroughly sound and should be of distinct value to the author's fellow practitioners.

Quatre cents consultations médicales.

Pour les maladies des enfants. Ninth edition. By Dr. JULES COMBY, Médecin Honoraire de l'Hôpital des Enfants-Malades. Paris: Masson et Cie. Pp. 551. Fr.36.

THE ninth edition of this book is larger than its predecessors and covers the whole range of children's diseases, medical and surgical. It is arranged alphabetically, a brief synopsis being given of the clinical features of the condition referred to, with the lines of treatment recommended. Prescriptions are set out in detail. As a book of reference for treatment, particularly of emergencies, this book should continue to fulfil a useful function.

Analyses médicales pratiques.

By RENÉ CLOGNE, Ex-Chef de Laboratoire à la Faculté de Médecine de Paris; Docteur en Pharmacie de L'Université de Paris, Lauréat de l'Académie de Médecine. Paris: Librairie Le François. Pp. 472. Fr.32.

THIS book was written for the purpose of providing a simple account of the methods of performing chemical analyses in the laboratory. A detailed description is given of each test and also a list of the necessary materials and of the figures normally obtained. Mostly the methods described are not those used in England or America and in some respects the book is old-fashioned. The author has included in this third edition two new chapters one on bacteriology and the other on parasitology, where the more common types of bacteria are discussed and the media in which they may most easily be discerned. In other respects the book does not differ materially from its former editions.

Erratum.—In the article on the Significance and Value of Examinations of Milk by Dr. Thomas Orr which has recently been reprinted from THE LANCET and published in Vol. II. of the collected articles on Clinical Interpretation of Aids to Diagnosis, the minimum figure for non-fatty solids in milk allowed by the Sale of Milk Regulations, 1901, should be 8·5 and not 8·7 (pp. 127 and 129).

THE LANCET.

LONDON: SATURDAY, JANUARY 9, 1932.

WOMEN AND NATIONAL HEALTH INSURANCE.

THE third quinquennial valuation of approved cieties made by the Government Actuary. Sir FRED WATSON. under the terms of the National ealth Insurance Act. 1924. which was summarised in THE LANCET of Dec. 26th. reveals a squieting state of affairs and raises problems of eat medical importance. Since the second valuan in 1923. a satisfactory aggregate surplus has cumulated. but the solvency of certain sections the scheme (a matter which touches the interest every citizen) is gravely jeopardised by certain ctors which have assumed unexpected importce. The survey covered 7600 approved societies d branches and an insured population of .380.143. of whom 5.427.121 were women. Of ese societies 7001 showed surpluses. the average rplus per member being £2·41. In 189 societies. ith a membership of 435,869. the assets and bilities were equal. In 418 societies and branches e deficit was £847,667, or an average of £1·17 r member.

This not unfavourable general picture is marred the unsatisfactory state of the women's societies. was pointed out at the second valuation that e women were making much heavier demands on e sickness and disablement funds than the men embers. and as a consequence of this warning paration has taken place to such an extent that 2 per cent. of the insured population are now nrolled in societies restricted to one sex only. t is now shown that in units insuring men only he average surplus is £2·76 per head. whereas the women's societies the corresponding figure £1·11, the "total retrogression" of the funds such societies since the last valuation amounting to £640.000. Further. the men's societies have en able to give valuable additional benefits o 88 per cent. of the male insured population, and he women's societies to only 38 per cent. of omen. Even this proportion cannot be maintained in the future. The reason for the disrepancy is simply explained, by the fact that the ickness and disablement claims of women are verywhere in excess of those made by men. and n the case of married women (who constitute 21 per cent. of the whole). grossly in excess. Between 1923 and 1927 there was a general rise in sickness laims. doubtless explained mainly by the economic ituation: the men's claims rose by about 13 per ent., but the single women's claims increased by 29 per cent.. and the married women's by 42 per ent. In the case of disablement benefit the respective increases were 54 per cent. and 87 per cent. respectively. The position is growing more serious as the proportion of women is relatively increasing: the costly married woman worker tends to stay longer in insurance. The insured population shows a gain of 10·3 per cent. of men, 10·9 per cent. of single women. and 23·8 per cent. of married women since the last valuation. In estimating future claims the Government Actuary has been compelled to allow for 25 per cent. more weeks of sickness benefit and 65 per cent. more weeks' disablement benefit for single women than for men. and for the married women 140 per cent. more sickness benefit and 60 per cent. more disablement benefit than for men. Taking both benefits together the cost provided is 60 per cent. more for all women than it would have been if the male rate of sickness and disablement had been applicable.

The report does not deal with the medical aspects of the situation. and evidently regards the great excess of liabilities incurred by the female worker as a permanent and possibly increasing factor in the situation. There is. however, a strong case for further investigation before this attitude is accepted by the medical profession with complacency. That a certain balance will pile up against the woman worker is apparently inevitable. It is well established that all investigations show a higher sickness-rate for women than for men in industry. Even among the professional classes the data, though scanty, point in the same direction. In a valuable study of "The Sickness Data of Elementary School Teachers in London. 1914–1919." by Mr. J. Y. HART. B.Sc.,[1] it was found that "sex was the most important factor in the illness of teachers. The mean illness of men teachers was 4·6 days a year for the period 1914–19. and the corresponding figures for single women and married women are 8·2 and 9·3 respectively." A further study of the causes and incidence of permanent disablement in teachers[2] showed that one woman teacher in 194 retired disabled. and one male teacher in 525; in other words. that a woman teacher is more than twice as likely to retire on health grounds as a man, but the risk is not in either case serious. Even with these known results of investigation before us the findings of the National Insurance Report are startling and disappointing. Modern education and training in hygiene had. it was commonly supposed. wrought an immense improvement in the health of this generation of young women. The reports of the elementary school medical service show a steady record of improvement. and the athletic triumphs of women in every field they have entered suggest a rising rather than a falling standard of physical efficiency. Nor does ordinary clinic experience suggest that the young woman of to-day in any class is a physical weakling. Within recent years certain diseases such as chlorosis and dysmenorrhœa have practically disappeared as a cause of periodic disability in

LEWIS'S PUBLICATIONS

THE

Extra Pharmacopoeia

By **W. HARRISON MARTINDALE, Ph.D.**

Vol. I., 27s. 6d. net; postage 6d. **Vol. II., 22s. 6d. net** ; postage 4d.
The Complete Work 50s. net, post free
Nineteenth Edition. ***In Two Volumes.***

Vol. I. (1928) deals chiefly with Treatment, giving the important issues as to CLINICAL USE of all modern CHEMICALS and DRUGS, characters, dosage, methods of prescribing, &c. Vol. II. (1929) COMPLETES THE SET. It is concerned with INVESTIGATIONS, EXPERIMENTAL RESEARCH, DIAGNOSIS, and a large amount of new matter in medicine and allied sciences.

BRIT. MED. JOURN., Nov. 2nd, 1929, says: "Has a well-established reputation as a most useful and convenient work of reference."
THE LANCET, Nov. 2nd, 1929, says: "A clear and authoritative publication of the highest value."

An up-to-date Book for everything on the Therapeutic Use of Drugs. It embodies the Latest and Most Varied Information on Chemistry, Pharmacy, Therapy, and numerous other subjects.

JUST PUBLISHED. With 12 Figures. Crown 8vo. **6s.** net; postage 5d.

culiar value in this country and in others where e specimens would not have been obtainable in rge numbers, because the spine may not be moved from bodies at autopsy.

The intervertebral disc is regarded by SCHMORL consisting of three parts, the nucleus pulposus, e annulus lamellosus, and the cartilage plate. he annulus lamellosus is arranged in a series of rong fibrous rings arising from the matrix of the rtilage plate and inserted in various points round the rim of the vertebræ, and is attached ith particular strength to the anterior longitu-inal ligament. It serves to resist tension and rsion, and acts as a capsule to the nucleus pulposus. This nucleus is a gelatinous mass, being a mnant of the notochord, and is under great ressure. Its function is to distribute weight, to ct as a shock absorber, and to be a pivot around hich all the movements of one vertebra on another akes place. The cartilage plate covers the per-rated area of the articular surface of the vertebral odies, and its function is to resist pressure and rotect the spongy bone. Taken as a whole the tervertebral disc is like a powerful spring cushion, here the tension of the spring depends upon the xistence of the outer cover; if this happens to ive way the tension within is reduced. As might e expected, therefore, the resistance of the carti-age plate, when healthy, to all kinds of injurious nfluences, both infective and traumatic, is very reat. When discussing the histology of these artilage plates Dr. BEADLE points out, however, hat in more than half the cases examined fissures an be seen running right through the substance f the plate into the bone; the conclusion drawn s that though normally very resistant, these lates are particularly prone to degenerative hanges, accentuated no doubt by repeated minor njuries during the course of a normal active life.

The practical importance of these fissures is hat they allow the substance of the nucleus pulposus gradually to prolapse through into the spongy bone. This observation was first made by SCHMORL in 1927, and the condition is found in bout 38 per cent. of the spines examined. The ge-incidence of these nuclear prolapses is interesting. Between the ages of 18 and 59 they are manifest in 40 per cent. of male and 20 per cent. of female subjects. In subjects over 60 this percentage is almost reversed, being 23 per cent. for male and 44 per cent. for female subjects. The interpretation placed on this curious change in incidence is that after the retiring age for men women continue their arduous household duties, and inflict a series of mild traumata on their degenerating cartilage plates which tends to produce in them, at a later age, the condition which is commoner in men before the age of 60. In young people reactive changes occur producing an area of sclerosed bone around the prolapse which offers a resistance to its further progress. But in the aged, where bone-forming processes are less active, inflammatory changes occur and the granulation tissue destroys the prolapsed nucleus, and even extends into the disc itself. In this way the disc gradually becomes converted into non-resilient fibrous tissue; when this takes place all shocks are transmitted from bone to bone, and osteophytic lipping occurs.

These observations on nuclear prolapse are of particular interest in connexion with adolescent kyphosis, a condition which in this country is usually regarded as being due to vertebral epiphysitis. According to Dr. BEADLE, when growth is still active, unless pressure changes are evenly distributed over the whole surface of a vertebra, the constant assumption of an attitude such as bending over books, or some manual occupation, tends to lead to alteration in the shape of the bone according to the well-known laws of bone growth. This alteration does not happen in the spine of a healthy child, because the intervertebral disc is so flexible as to enable it to distribute pressure over the whole surface in a perfectly uniform way, in whatever position the vertebræ may lie. The nucleus pulposus also has a distributing function of this kind, but if this nucleus has prolapsed into the bone it cannot fulfil this function. Consequently greater weight is borne anteriorly than posteriorly, with the result that eventually the vertebræ becomes wedged-shaped. In such cases the primary cause of the prolapse may be a congenital one, but Dr. BEADLE quotes the opinion of SCHEUERMANN [2] that the beginning of a kyphosis may sometimes be traced back to a bout of hard work, and suggests that in some cases there may be an abnormal vulnerability of the cartilage plate rendering it liable to become fissured by repeated slight traumata, and so to allow the nucleus pulposus to prolapse. The presence of a prolapse does not of itself produce kyphosis, but the combination of prolapse with the constant assumption of one attitude, either during work or play, at a time when the vertebræ are actively growing, may, it is held, give rise to the clinical picture of adolescent kyphosis. If this sequence is accepted, it follows that for certain children arduous sports should be prohibited, though it is not clear how those who are specially liable to early degenerative changes in the disc could be recognised. The thesis of this work is that this tendency is far more common than is generally supposed. The assumption of the erect attitude is a relatively recent event in the history of evolution, and the spine is still showing a reluctance to adapt itself to its altered position.

The beautiful plates which illustrate this monograph are certainly convincing, and it seems likely that Prof. SCHMORL has opened up a new line of investigation which may be followed with profit. The conclusion drawn from his studies of spinal deformity by Dr. BEADLE is a conviction of the paramount importance of the intervertebral discs in the preservation of the normal form of the spine during the infinite changes of shape, compressions, extensions, and torsions it undergoes in functional life. The severity of the strain they have to bear leads them to yield to senile changes long before these appear in other tissues; and where these changes have occurred, the spine becomes stiff and permanently deformed.

training colleges, nurses' homes, and factories. It is indeed incredible that preventive medicine has done nothing, or can do nothing more to close the gap which still yawns between the physical efficiency (measured in terms of sickness-rate) of men and of women in industry. Even in an age when commissions and committees of inquiry have been overdone, it might be sound economy to inquire more deeply into the precise nature of the excess of sickness in women, and whether it is in fact being prevented by the welfare work and improved hygienic conditions which obtain to-day in certain factories and offices. The experience of the Ministry of Munitions and the women's services during the war certainly suggested that the health of women workers was susceptible to improvement under good conditions.

Leaving aside the possibilities of reform in the future, the situation to be faced by the approved societies is undoubtedly grave, and Sir ALFRED WATSON strongly urges the application of two remedies. He suggests that the separation between male and female insured persons should be "still further developed" in order to "correct the injustice to male members." He further demands that the contributions of women members be increased or that their benefits be reduced to bring the finances of their societies on to a sound basis. The necessity for some such measure is obvious, but as has recently been pointed out[3] it is by no means clear why the single women should have to bear the entire burden of the married women's excess claims. If the young married woman worker constitutes a serious drain on the funds of her society, it is no doubt partly because of sickness and minor disabilities associated with pregnancy, which are singularly difficult to check. There are many days or even weeks in the course of a perfectly normal pregnancy when a woman is genuinely unfit to turn out in the early morning or to keep on her feet all day, although she is quite able to get through ordinary household duties in her own time; no system of medical certification can protect funds effectively against these extra claims. Moreover, the married woman is apt to have a double burden of household duties in addition to her industrial work, which may prove a serious physical strain on the less robust women. Most difficult to assess, but possibly most important of all, is the undeniable fact that for obvious reasons it is more often to the interest of the married woman to stay at home than it is for the man or the single woman. The "psychological moment," in the proper sense of that much-abused term, tends to push the insured married woman into invalidity. That this is not due to a peculiarly feminine failing but to a universal human weakness is frankly recognised by the *National Insurance Gazette*, which points out: "No health or unemployment insurance scheme can do any good with members or policy-holders who prefer to be claimants. It is an elementary principle in insurance. No fire insurance company would knowingly issue a policy to a person who preferred to have a fire." In equity it would thus appear that if the married woman worker is to be grouped with any other class it should be with the married men. For such part of the excess claims as is due to pregnancy they are surely responsible rather than the single women, and where the excess is caused by excessive devotion to home interests presumably they and not the single women reap the benefit. Administratively it may be more convenient to group all the women together, but it is bad administration to penalise a class unfairly for the convenience of administrators.

The report leaves the strong impression that there is much to be said for the suggestion, often advanced by insurance experts, that married women should be taken out of the insurance scheme altogether, and should constitute a special group of "exempted persons." Their health is of especial concern to the nation and should be adequately provided for, but not by a scheme which encourages wasteful claims, and threatens other classes of workers with unjust curtailment of benefits or financial ruin. It has been necessary to reconsider seriously the position of married women under the Unemployment Insurance scheme, and the time has come when in the interests of the nation it appears equally necessary to readjust their position in regard to National Health Insurance.

◆

THE FUNCTIONS OF THE INTERVERTEBRAL DISCS.

IN this country the work of Prof. GEORG SCHMORL, of Dresden, on the pathology of the spine has not received the recognition it deserves, though in France, mainly through the efforts of J. CALVÉ and M. GALLAND, the importance of his observations has been widely appreciated.[1] Since 1923 Prof. SCHMORL has collected some 7000 whole spines, and the conclusions he has reached from the detailed study of this material as a whole and of the vagaries of the intervertebral discs in particular are extremely instructive. Dr. O. A. BEADLE, while holding the Radcliffe Travelling Fellowship for 1929–31, has been working with Prof. SCHMORL, and has just published, under the auspices of the Medical Research Council, a report on the intervertebral discs embodying observations on their normal and morbid anatomy in relation to certain spinal deformities.[2] Dr. BEADLE points out in his introduction that though the results of the anatomical researches carried out in the pathological department of the Friedrichstädter Krankenhaus at Dresden have been published in a scattered way in various German journals, no connected account has appeared in any language of the interpretation placed on these results by those actually working in the department. This report is a first-hand description of specimens actually seen and handled by the author, and is not a mere summary of SCHMORL's publications. It has r Cecil Levita, late chairman of the London County uncil, who become K.C.V.O.; and among new ights, Mr. Halley Stewart, founder of the trust nd called after him, and Prof. Patrick Geddes, the teran sociologist. In the world of nursing, Annie dy Cowdray is appointed G.B.E. in recognition of r long work and many benefactions, while lesser nk in the same Order is conferred on the superinndent of the Queen's Institute of District Nursing, iss A. M. Peterkin, and two matrons of English ental hospitals, Miss E. E. Gardner and Miss A. J. ichardson. Sister F. M. D'Exeter, of Queen lexandra's Royal Naval Nursing Service, receives the .R.C., and Mrs. Katherine Cook, of Uganda, is romoted to be O.B.E. To all these and others hom we have not mentioned in this place we offer earty congratulations.

OBESITY AND WATER BALANCE.

CLINICIANS tend to be somewhat fatalistic about obesity, to assume that the fat person will continue o wax fat even when his food intake has been reduced below the normal maintenance level. A paper by L. H. Newburgh[1] helps to explain the origin of this superstition. Deposition of fat can only take place in one of two ways—either by diminished katabolism of issue fat, or by increased assimilation of the fat supplied by the diet. Concerning the first possibility there is no evidence that oxidation of fat is deficient in cases of obesity. Indeed, W. M. Boothby and I. Sandiford[2] have shown that the basal caloric output, per square metre of body surface, is normal in obese patients. If the caloric expenditure is normal, it follows from elementary physical laws that restriction of the caloric intake below minimal requirements must cause a loss of flesh. A loss of flesh, however, does not necessarily imply a loss of weight, and much of the prevailing confusion of ideas is due to failure to realise the importance of water balance in relation to changes in body-weight. The clinical determination of water balance is one of the most difficult problems in experimental medicine. Mere comparison of fluid intake with urine output is valueless, except in cases of gross œdema. Most solid foods contain a high proportion of water and the body also gains water from the combustion of the hydrogen of the assimilated foods. On the other hand water is lost, not only through the kidneys, but also in a large measure through the skin and lungs and the intestine. In his studies of obesity, Newburgh has measured these various fractions by intricate methods, and finds that a diet inadequate in caloric requirements always causes a loss of flesh, but that this loss may sometimes be entirely masked by coincident retention of water. He concludes that there is no specific metabolic abnormality in obesity and that all obesity is therefore "simple" obesity, indicating a failure of the primitive instinct to adjust the inflow of energy to bodily needs. He reminds us that, while an obese patient may, in all good faith, deny that he overeats, close cross-examination will often show that he is confusing food bulk with food value.

While Newburgh's work helps to clear away some misunderstandings, it does not offer a complete explanation of obesity. It may be, as he suggests, that the overnutrition is usually due to unconscious habitual overeating. Yet it would be unwise, in the absence of further evidence, to ignore the possibility that primary derangements of such organs as the pituitary and the hypothalamus are to some extent to blame.

A GUIDE TO THE ACTIVITY OF RHEUMATIC INFECTION.

THE importance of the sedimentation rate of the red cells as an indication of the presence or absence of active infection has long been recognised. Almost immediately after the introduction of the test by Fahraeus it was adopted as a means of following the course of pulmonary tuberculosis and it is now generally admitted that, provided too much attention is not paid to single examinations and the observer adopts a reasonably critical attitude, it is of considerable value in this condition. Hitherto, this has been almost the only field in which it has been consistently applied, but in our present issue Dr. Payne, working at the Hospital for Sick Children, and Drs. Bach and Gray Hill, working at St. Bartholomew's Hospital and at Queen Mary's Hospital, Carshalton, describe their application of the test to rheumatic infections in childhood. The practitioner dealing with a case of acute rheumatism in a child is faced, once the acute symptoms have subsided, with the dilemma that he may keep the patient invalided too long or may let him up too soon with resulting irremediable damage to the heart. Every practitioner of wide experience can think of children who have been allowed up too soon and in whom cardiac lesions have developed resulting in chronic invalidism and possibly in death; on the other hand, there are no doubt hundreds in bed at the present moment who might be up and about, and going on with their schooling, if only there were some reliable guide to the subsidence or otherwise of the acute inflammatory state. The results obtained independently by Dr. Payne and Drs. Bach and Gray Hill give good grounds for believing that in the sedimentation rate of the red cells we have the necessary criterion. These observers agree that the persistence of a sedimentation rate of less than 10 mm. in the first hour shows subsidence of the infection, while a higher rate is an indication for further rest in bed. Up to the present the sedimentation rate in its application to children has shared with most other "blood" tests the disability attaching to the withdrawal of large amounts of blood; in dealing with children none but the most hardened or those most assured of the benefits likely to accrue from the procedure can face this with equanimity. The technique described by Dr. Payne to some extent does away with this drawback and in the hands of reasonably careful workers should prove accurate enough for clinical purposes.

CARBON DIOXIDE AND SPINAL ANALGESIA.

THE use of carbon dioxide in connexion with anæsthetics, following chiefly from the work of J. S. Haldane and Yandell Henderson, is being repeatedly demonstrated and recommended. The latest contributions to the subject is a paper by C. A. Roeder[1] dealing with the aid which CO_2 can give in those cases, not very uncommon, in which respiration fails after intrathecal injection of an anæsthetic for spinal analgesia. The physiological explanation of both circulatory and respiratory failure in spinal analgesia is still variously given by different authorities. Roeder holds that respiratory failure

[1] Amer. Jour. Surg, November, 1931, p. 454.

CHRONIC LYMPHANGITIS AS THE CAUSE OF CANCER.

SOME twenty-five years ago Mr. SAMPSON HANDLEY demonstrated the importance of the lymphatic system in the spread of malignant disease, with a wealth of detail which left little room for doubt as to the general accuracy of his views. Since then he has become more and more impressed with the dominant part played by the lymphatic system in physiology and pathology, and his most recent contribution to the subject[1] is an exposition of his theory that chronic lymphangitis with its accompanying lymph-stasis is the actual cause of carcinoma.

Briefly, his theory is as follows. Chronic lymphangitis is the essential change brought about by practically all irritants, microbic, physical, and chemical. This is followed by lymph-stasis which in turn causes overgrowth of tissue and the formation of adenomata and papillomata, the precancerous hyperplasias. The starting-point of the theory is the pathology of lupus and the demonstration of the lymphangitis-papilloma-carcinoma sequence in lupus carcinoma, and it is supported by a mass of observations from other aspects of pathology. It is impossible to consider all the evidence in detail, and the reader must decide for himself how much of it will stand critical examination; but it is clear that it is not all of equal value. About some of Mr. HANDLEY's facts there will be no disagreement, others are disputed; and at times he seems to assign the same value to a supposition as would be given to a self-evident truth. For example, he regards it as proven that gastric ulcer is the precursor of gastric carcinoma; part of his argument rests on the assumption that the pigmented mole is derived from lymphatic endothelium; and he suggests that polypi of the bowel (and vesical papillomata) are most frequently due to a mild non-ulcerative tuberculous infection in childhood, though no proof of this supposition is offered, and the known incidence of tuberculosis and cancer of the intestine is opposed to it. In Mr. HANDLEY's view inflammatory reactions in the subcutaneous tissues seem to be dominated entirely by the lymphatics, and the changes in the tissues as a whole are purely secondary. Few people however will agree with this, nor will Mr. HANDLEY's use of the term granulation tissue be generally approved. And while no one who has seen an acute lymphangitis associated with a septic hand will deny that infection may spread by the lymphatic vessels, is this a justification for describing organisms which give rise to such infections as lymphophilic, and for assuming that the tissue reactions called forth by syphilis and tuberculosis are essentially the same? Without going into the question of the formation of tissue lymph and its circulation—a highly complex business—it may be asked whether stagnant lymph is such a good nutrient medium as Mr. HANDLEY presumes. We know little about it beyond the fact that it must be overcharged with the products of cell metabolism, but it seems unlikely that such a fluid should possess the factors which stimulate the growth of epithelium; and in this connexion it is significant that in one form of Paget's disease of the nipple—that produced by obliteration of the cutaneous lymphatics and lymph-stasis—the secondary epithelial change is atrophic and not hypertrophic.

In his preface the author states that his book is not an armchair speculative essay and asks that the evidence he brings forward should be seriously considered. No one who knows and appreciates Mr. HANDLEY's work—and who does not?—will lightly disregard any observations he makes on the cancer problem. If we are not convinced of the truth of his theory, we are grateful to him for an interesting and stimulating deliverance.

[1] The Genesis of Cancer. By W. Sampson Handley, M.S. Lond., F.R.C.S., Vice-President of the Royal College of Surgeons. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1931. 21s.

ANNOTATIONS

NEW YEAR HONOURS.

THE list appearing on p. 104 shows that honours have been conferred this New Year on medical men and women who have won distinction in many different occupations. The first name is that of Major Walter Elliot, whose enlightened work in the House of Commons and in office is appropriately rewarded by appointment to the Privy Council. Dr. F. N. Kay Menzies, who has borne and is bearing heavy responsibilities in the organisation of London health services, becomes a Knight of the Order of the British Empire, in company with Dr. A. M. Daniel, whose privilege it is to be director of the National Gallery. First among the new knights in scientific attainment is Dr. H. H. Dale, secretary of the Royal Society and director of the National Institute of Medical Research, but in a different sphere we welcome equally the recognition of Mr. Buckston Browne's perspicacious benevolence towards the social life and future development of medicine. The name of Miss Edith Brown is less familiar in this country but her new rank as D.B.E. is as well deserved as it was little expected when she first went out to India to work in humble circumstances for Indian women. Suitable promotions to knighthood are those of Dr. John Weir, physician in-ordinary to the Prince of Wales, in the Victorian Order, and of Sir James Kingston Fowler, who becomes K.C.M.G. The long and useful life work of Sir Leonard Rogers is fittingly marked by knighthood in the Order of the Star of India. Outside the strict limits of our profession we find with pleasure the names of Miss Harriette Chick, D.Sc., of the Lister Institute, who is appointed C.B.E.; Mr. Henry S. Wellcome, LL.D., a valuable friend of medicine, who is knighted, and Mr. E. W. Morris, of the London Hospital, and Mr. E. D. Simon, M.P., for a brief time parliamentary secretary to the Ministry of Health, who receive the same honour. Other notable names are those of Sir Malcolm Delevingne, who represents Great Britain in conferences on dangerous drugs, and an ingenious way. A tube containing a mercury droplet was introduced into the instrument, and by photographing the movements of the droplet the changes in the blood current could be ascertained. These experiments disclosed a striking difference from the first series of observations; a forward movement of the mercury droplet occurred not only during diastole, but again during the early part of systole. This suggested that an increased coronary flow took place during early systole, as well as in diastole, as Rabatel had claimed. This, however, is an unjustifiable deduction, for the same forward systolic movement of the droplet was found when the coronary capillaries were blocked; it is determined by the elastic expansion of the coronary artery caused by the rise in pressure which accompanies systole, but not by an increased flow through the organ. Thus in a series of beautiful experiments are the inconsistencies between the results of various observers settled, and the belief that the main blood flow through the coronary system occurs during diastole is confirmed.

PLASTIC SURGERY OF THE NOSE.

THE nose is perhaps the most conspicuous feature of the face, and any exaggeration, loss, or deformity thereof becomes an object of undesired attention, and is likely as well to produce disquieting self-consciousness. The extent to which individual noses vary in size and shape without transgressing the limits of the normal is very great, but, to be acceptable, the nose must be in harmony with the features among which it has its setting. The surgeon may be consulted, by reason of appearance or impaired function, concerning the possibility and advisability of changing or restoring a nose which is not satisfactory. The task of giving advice on such a matter is not as simple as it may appear, and we welcome two papers, containing much useful information, which have recently appeared.[1] The first, by G. B. New and F. A. Figi of the Mayo Clinic, deals with the reconstruction of the larger defects by means of pedicled flaps, usually taken from the forehead. The details of the method have been immensely improved since its original introduction as the "Indian" operation very many years ago, in the care and accuracy with which the flaps are fashioned, and more particularly in the adoption of the principle that all flaps covering a cavity must have a lining of skin on both surfaces. New and Figi lay stress on the importance of the mental attitude of the patient in these operations, as in any plastic procedure for improving personal appearance, and state that the operation must be requested by the patient rather than submitted to because advised by the surgeon; for otherwise the patient is not likely to be pleased with even a good result and will chafe at the length of time and the number of operations required. In the second of these papers, by V. P. Blair and J. B. Brown, the correction of smaller cosmetic defects, as well as of the larger deformities, is discussed, and in these the mood of the patient assumes even larger proportions. As they say, it is a general working rule that, the more pronounced the deformity, the more likely is a reasonably good result to be acceptable; but, conversely, it is well to be cautious about embarking upon the correction of slight defects. Adolescents of both sexes, especially those who have no regular employment, are more apt to be over-particular than older people. A patient's inability to state clearly the particular thing that displeases him should excite the surgeon's doubt of his own ability to satisfy; this same uncertainty should also arouse the suspicion that the real fault may not lie in the nose at all, for not seldom a too short or too large chin may be the real but unrecognised offender by disturbing the balance of the features. The all-important details of the numerous plastic procedures are too intricate for brief consideration, and our object here is rather to emphasise the importance of considering the patient's psychological reactions to his, or her, deformity.

AN UNUSUAL TREATMENT FOR PEPTIC ULCER.

EVEN if we believe that the thorough treatment of peptic ulcer by diet and alkalis, on the lines first laid down by Sippy, gives far better results than were achieved before it was introduced, and even if we are unstinted in our admiration of the surgical treatment of chronic peptic ulcer when the operation is performed by a first-class surgeon, we must admit that both methods leave a proportion of inexplicable failures which are a cause of distress to patient and practitioner alike. The ulcer which yields readily to medical treatment is perhaps the ulcer which gives also the most satisfactory results when treated surgically, and, conversely, the very extensive chronic ulcer which does not prove readily removable at operation presents an equally difficult therapeutic problem to the physician. These facts lend additional importance to any novel therapeutic procedure which is backed by authoritative testimony to its frequent or occasional efficacy. On another page of this issue will be found a paper by Prof. Glaessner, of Vienna, who has for some years been using injections of pepsin in the treatment of gastric and duodenal ulcer. He thinks there is evidence of a biological difference between the gastric juice of normal persons and of those suffering from peptic ulcer. On injecting gastric juice from such subjects beneath the skin of a guinea-pig or painting the same substance on the cornea of the animals, he finds that the erosion caused by the juice from an ulcer patient is far more extensive and far slower in healing. Again, he has succeeded in producing artificial ulcers of the skin and mucous membranes of rats, guinea-pigs, and rabbits by the intracutaneous or intramuscular injection of gastric hydrochloric acid, and he has found that the subcutaneous injection of pepsin will notably accelerate healing in such cases. Acting on the results of these (perhaps somewhat scantily controlled) experiments, he has passed on to the treatment of ulcer in human beings by similar injections. The pepsin employed is not sterilised, but is filtered through porcelain under pressure, to rid it of albumin; diluted carbolic acid is added as an antiseptic and a 1 per cent. solution is finally obtained. The injections are said to be harmless and painless. Each patient is given about 30 injections twice yearly, the amount increasing as the series proceeds. Six hundred cases have been treated, and Prof. Glaessner claims that very good results were obtained in fully two-thirds of the 130 which were thoroughly controlled. Objective and subjective cure was brought about in these, although in at least half of them no change was observed in the acid secretion of the stomach before and after treatment. Of all his cases only 6 per cent. required surgical interference.

In assessing the value of these injections it must not be forgotten that certain routine medical treatment was employed simultaneously. Olive oil was given before meals, and an alkaline powder containing bismuth was taken in addition. Preparations of is due either to paralysis of the phrenic and intercostal nerves, or else to ischæmia of the respiratory centre, owing to extreme fall of blood pressure produced by the injection. When the first cause is at work only artificial respiration can effectively remove the disability, but when the second cause is alone active then inhalations of carbon dioxide are of great service. Roeder gives CO_2 during the time of spinal anæsthesia, and, if necessary, two hours afterwards. This he says may carry the patient over an acute emergency, for by making the respiration continue the thorax "acts as a temporary heart providing that the motor nerves of respiration are not blocked." Inhalations of 4 per cent. CO_2 increase the pulse-rate and raise the blood pressure. A percentage of 10 causes headache and mental confusion. With higher percentages the heart-rate drops and the blood pressure, temporarily raised, soon falls with cessation of respiration. Roeder is of opinion that so far from doing away with the necessity for an anæsthetist, spinal anæsthesia demands one of greater training owing to the greater frequency of serious complications. And he should be armed with apparatus for artificial insufflation of the lungs with CO_2 and oxygen. In most operating theatres nowadays cylinders are available containing 5 or 7 per cent. carbon dioxide in oxygen. In private practice, when perhaps this kind of apparatus is not at hand or cannot conveniently be used, the anæsthetist can easily carry his own carbon dioxide by means of an excellent portable apparatus now on the market[2] consisting of small metal cylinders about 7 inches long and less than an inch in diameter, fitted into a neat holder. Delivery of the gas is made very simple; the apparatus is easy to work; it does not take up much room in the doctor's bag; and is not likely to be exhausted by use in one case. The cylinders are, moreover, inexpensive in the first place, and can be refilled at a very small charge.

INFECTION AND HEPATIC FUNCTION.

As was emphasised in a recent discussion at the Medical Society of London,[3] the great majority of tests of liver function must, from the clinical point of view, be regarded as valueless. Indeed probably only the van den Bergh and the galactose or lævulose tolerance tests can be said to have any practical application, and that a limited one. The reason for this is partly the complexity and number of functions of the liver, partly the great reserve powers of the organ, and partly, too, the fact that several of the activities previously ascribed exclusively to the liver are also carried out by the extra-hepatic reticulo-endothelial system. Experimental evidence indicates for instance that the excretion of bromsulphthalein (a test of liver function formerly advocated and now largely discarded) is influenced both by blocking the reticulo-endothelial system with Indian ink or by reducing its functional capacity by removal of the spleen (F. Schellong and B. Eisler[4]). An attempt to correlate the results of this test with estimations of serum bilirubin in health and in various infective conditions is included by C. W. Herlitz[5] in his recent investigation carried out on groups of children between the ages of 6 months and 12 years. He found that while the bilirubin values were raised in 65 per cent. of the infections due to streptococci, they were normal in the great majority of respiratory or urinary infections due to other organisms. Bromsulphthalein excretion, however, which was studied in a smaller series of cases, showed impairment in 12 out of 15 infective cases, irrespective of the type of organism responsible. There was thus no parallelism between the results of this test and the bilirubin content of the blood. This was further illustrated by the fact that normal bromsulphthalein excretion occurred in cases of hæmolytic jaundice—a condition in which the functional activity of the reticulo-endothelial system is probably unimpaired. In view of his own findings and of the experimental evidence, Herlitz concludes that the bromsulphthalein test is a test of the function of the reticulo-endothelial system rather than specific for the liver cells. He also thinks that hyperbilirubinæmia, when it appears in infective conditions, may be attributed primarily to increased destruction and formation of bile-pigments in the reticulo-endothelial system, the increase being inadequately compensated for by increased excretion

THE CORONARY BLOOD FLOW.

EXPERIMENTAL work on the blood flow through the coronary artery when it is perfused at a constant pressure has shown that the flow is either stopped or greatly diminished during systole, and that the main flow takes place during diastole. But in the intact animal the coronary system is subjected to perfusion not at a constant pressure, but at one which varies widely during each cardiac cycle according to the changes in the intra-aortic pressure. Observations made 60 years ago by F. Rabatel and recently by M. Hochrein and his co-workers on the circulation through coronaries remaining in connexion with the aorta has given results which are the reverse of those obtained when the artery is perfused at a constant pressure. It was found that besides an increased flow in diastole there was an increased forward movement of blood in the early phase of systole. This was attributed to the increased pressure within the aorta which occurs at this time. These discrepancies are settled by the experiments of G. V. Anrep and his co-workers.[1] They first determined the maximum pressure in the artificially perfused coronary artery at which systole still arrested the flow. This was found to be considerably in excess of the maximum aortic systolic pressure; and in no case, whatever the difference between the aortic systolic pressure and the perfusion pressure, was an increased coronary flow observed to take place during systole. It is obvious from this experiment that the flow must be arrested in systole in an aorta-perfused coronary. This conclusion was confirmed by experiments on the aorta-perfused coronary in which a stromuhr was inserted between the aorta and the coronary cannula. Under these conditions it was found that the coronary pressure is the same in systole as when it is clamped, again indicating that the contraction of the heart stops its arterial circulation. A considerable rise in systolic pressure had very little effect on the flow, but a slight rise in diastolic pressure caused a considerable increase in the flow—for example, a rise of 4 mm. in pressure increased the volume by more than 10 per cent. The inevitable conclusion to be drawn from all these experiments is that the volume of the blood flow through the coronary system is maximal during diastole and minimal during systole. Further analysis of the rapid and detailed changes in the flow was made with the stromuhr modified in

SPECIAL ARTICLES

CATTLE RINGWORM IN MAN.

By George Ashton, M.D., M.R.C.P.

The Ministry of Health recently had occasion to consider the question of the prevalence in this country of cattle ringworm in man. The literature on the subject was consulted, and further information obtained through a special inquiry made by the regional medical staff of the Ministry of Health, who interviewed 384 insurance practitioners in England and Wales whose practices were thought likely to afford opportunities of observing persons affected by the disease. It devolved upon me to collate and summarise the information thus obtained, and it is thought that the following summary may be of interest more especially to medical officers of health and practitioners in agricultural areas.

Historical.—At the end of the eighteenth century there were references to contagious skin affections implicating the body, head, and shoulders of animals, and in 1820, Ernst, a veterinary surgeon in the canton of Zurich, described a case in which a young girl was infected from a cow. Carrère, in 1838, noted that the virus might remain for a long time in stables and advised burning harness and cleaning any other objects, which might have been rubbed by the infected animals. Letenneur pointed out, at about the same time, that cattle ringworm is most common in the spring after the animals have spent a long time in their winter quarters. He advocated quarantine of the infected animals. Malmsten, in 1845, discovered a vegetable parasite, which he then called the "Trichophyton tonsurans" and which belongs *to the hyphomycetes* or moulds. A similar fungus was identified by Gerlach, in 1857, as the cause of ringworm in domestic animals.

The fungi causing diseases of the hair and skin can be divided into two groups, the microsporons and the trichophytons, distinguishable by differences in mycelium and in fructification. The microsporons, which are responsible for the common forms of ringworm of the scalp, are not (with quite unimportant exceptions) concerned in the ringworms of animals which are communicable to man. The trichophytons may be classified as follows :—

(1) *T. endothrix*, affecting the interior of the hair and not primarily the skin, and perhaps exclusively of human origin (large-spored ringworm of the scalp); there are several varieties (? species) including *T. crateriforme* of Bodin (1902), which is possibly the equivalent of Malmsten's "T. tonsurans."

(2) *T. neo-endothrix*, intermediate in mycological character between the human and animal classes and affecting both hair and skin in human beings; one variety has been found in cats; others have not been proved *to occur in animals.*

(3) *T. ectothrix*, the class which chiefly gives rise to disease in animals. These *fungi affect* chiefly the skin and produce in man the typical circinate lesions of cattle ringworm. One group of these *fungi has small spores* resembling those of the microsporons and contains several varieties (? species). This group attacks horses and dogs. The other group has large spores and also contains several varieties among which are some causing *ringworm both* in cattle and horses. Of this group, and particularly common in cattle, are the faviform varieties, *T. album* and *T. discoides*, which produce in culture a mycelium *like that of favus*; but the lesions are characteristically *ringworm* in character and the fructification forms of the fungus of favus are absent.

THE INFECTION IN ANIMALS.

Incidence.—Bovine animals are most readily affected with ringworm, especially young stock animals. Calves are the chief sufferers, and the disease seems to be relatively rare in dairy animals. Dogs and horses are also susceptible. Goats and cats suffer more rarely; pigs and sheep hardly at all. Cattle ringworm is fairly common in this country, but seems *to be limited to certain districts.* It also appears to be more prevalent in England, Holland, France, and Switzerland than in other parts of Europe.

Mode of infection.—The transfer of the fungi of cattle ringworm from the infected cattle to other cattle occurs: (*a*) By direct contact, especially during pasturage. Bulls, in particular, may transmit the infection to a whole herd. (*b*) By indirect contact through the indiscriminate use of infected combs, brushes, clipping-machines &c., or by healthy cattle rubbing against *infected rubbing-posts, stalls, railings,* and gates.

Clinical manifestations.—At the commencement of the disease the characteristic signs are clearly defined circular areas of cutaneous inflammation, either hairless or studded with broken hair; these areas are generally seen on the head and neck and more rarely are scattered over the whole body. Their frequency on the head and neck is largely due to cattle scratching and biting each other on the head and neck, and to the use of infected rubbing-posts. The patches, which are at first the size of a pea, extend at the circumference and may attain the size of a crown-piece or the palm of the hand. They are usually discrete, but may coalesce to form larger areas. Later, vesicles are formed which quickly burst and dry up to form thick crusts and scabs, which may be of a greyish-white or yellowish colour and of a leathery consistence. The presence of these scabs no doubt accounts for the disease being known popularly as "dry scab" and "scab mange." Healing usually proceeds under the scabs, which gradually fall off, leaving slightly scurfy bald patches upon which the hair slowly grows again. On its first appearance, and also during the healing process, the eruption causes itching. The eruption generally lasts from 6 to 12 weeks, but if the normal course is disturbed by rubbing or scratching, fresh outbreaks occur within the healed patches and the ailment may be prolonged for 6 or 12 months or even longer.

THE INFECTION IN MAN.

Incidence.—88 of the 384 practitioners interviewed by the regional medical staff stated that they had not seen any cases of cattle ringworm in man. Of the 296 practitioners who had seen cases, 132 volunteered the statement that the disease rarely came under their observation, the number of cases seen varying from two cases in 25 years to five in one year. Several expressed surprise that, considering the large number of people exposed to infection, the disease did not come more often under their observation. The disease is commonest in persons who work *amongst cattle, such as farm labourers.* Farm workers who handle calves are particularly likely to be infected, the disease being, as already stated, very common in calves, especially during the colder months when they are confined indoors. Ringworm is not so common in milch cows, and for this reason milkmaids and dairymaids are not especially liable to contract the disease. Many cases of ringworm derived from horses and mules were seen in men *attached to mounted units and transport services* during the late war.

Mode of infection.—The disease in man is generally derived directly from infected cattle, but infection sometimes arises indirectly from contact of the hands and wrists with walls, gates, posts, &c., against which infected cattle have rubbed.

Clinical manifestations.—The disease appears to be belladonna and sodium bicarbonate were completely avoided. If there had been no hæmorrhage a mixed diet was utilised at first, but in some severe cases milk and cream was prescribed; and in general the mixed diet described by Prof. Glaessner appears to approximate to that recommended by the majority of physicians in this country. In these circumstances it may well be argued that the pepsin injections played a secondary part in the treatment, but the claims of Prof. Glaessner cannot be overlooked, especially as he has found his method of treatment of use in such resistant conditions as jejunal and œsophageal ulcer, as well as for the simpler lesions in more usual situations. As a practical suggestion the method seems to deserve investigation in this country, while its theoretical aspect is of interest in relation to some of the observations on hydrochloric acid mentioned in our leading article last week.

THE LYMPHOID TISSUE IN THE LUNG.

AN interesting communication on the lymphoid tissue in the lung, by Drs. F. W. Simson and A. Sutherland Strachan, reaches us from the South African Institute for Medical Research.[1] The authors believe that the lymphatic apparatus of the lung is the decisive factor in the localisation of inhaled dust particles, and in the development of pneumokoniosis. According to their observations, dust-laden phagocytes pass from the alveoli of the lung to small intrapulmonary collections of lymphoid tissue, and from these into the lymphatic vessels which drain into the extra-pulmonary lymph nodes. Presumably the escape of phagocytes must be fairly complete, for the tracheo-bronchial lymph nodes may show typical silicotic fibrosis before recognisable changes occur in the lung itself. Nevertheless, a certain amount of dust is retained in the lung, and this progressively increases with the gradual obliteration of the lymph drainage system. The demonstration of the localisation of lymphoid tissue in the lung is by no means easy. It is widely scattered and consists of minute aggregations of lymphoid cells with, possibly, a supporting reticulum, but the nodules are indefinite and difficult to distinguish. They may be more prominent in congestive and inflammatory states of the lung, but in these conditions it is impossible to be certain that recognisable collections of lymphocytes represent a simple exaggeration of the normal distribution; they may well be pathological new formations. In the search for material suitable for their needs, it occurred to the authors that the lungs of children said to have died from "status lymphaticus" might present such a hyperplasia of the normal lymphoid tissue as to make its distribution clear. Whether or not the diagnosis of the cause of death in these cases could be substantiated is immaterial; it is sufficient that the authors obtained lungs which, while apparently free from changes due to previous disease, presented a very definite increase of lymphoid tissue. And after careful comparison with many other lungs it seemed certain that these hyperplastic areas were normal in their distribution. Their preparations, some of which are admirably illustrated in the paper, have convinced Dr. Simson and Dr. Strachan that previous descriptions of the distribution of lymphoid tissue in the lung are in need of modification. It has been described, for example, as occurring along the course of the pulmonary artery and at the junction of the smaller tributaries with the larger branches of the pulmonary veins. But in this series of cases, the distribution of lymphoid tissue is in strict relation with the respiratory tract, and is in no way related to the vascular system except in situations where air passages and blood-vessels come into juxtaposition; and even here it seems clear that the association is in no sense physiological but purely anatomical. Lymph channels traverse the lung, of course, in close relation with blood-vessels, but in no part of their course do they appear to be interrupted by lymph nodes; these appear to be functionally related to the air tubes, and the air tubes alone. The authors discuss the application of their observations to the localisation of infections as well as dust, and suggest that chronic tuberculosis of the lung affects first the lymphoid tissue when the infecting dose is minimal. Further work on these lines is in progress, and the subject appears to be one well worth pursuing.

A GREAT JOURNALIST.

THE bond between editors, whether of technical journals or of daily newspapers, is, or should be, a common ideal. Whether the screen on which they display the moving picture of their times is large or small, neither editors nor the journals they conduct will gain recognition or esteem unless they see to it that the light which illuminates the picture throws a steady beam of truth. The public from whom they seek support may be drawn from all classes and schools of thought, or may follow a special discipline, but it is quick, and growing rapidly quicker, to detect distortions, omissions, or artificial devices in the presentation of facts. These reflections arise from the news of the death of a great journalist, C. P. Scott. Every journalist has been assailed by the temptation to adjust facts to support a theory or to fit a policy, and learns early to regard integrity in this respect as a major virtue in his colleagues. This virtue, with many others, was in Scott, and his good repute will long be a public memory.

Mr. Wilfred Trotter, F.R.S., has succeeded Sir Hugh Rigby as sergeant-surgeon to the King, and Sir Hugh becomes an honorary surgeon to His Majesty.

Dr. George Proctor Middleton has been appointed surgeon apothecary to H.M. Household at Balmoral, in place of Sir Alexander Hendry, who has resigned.

The King has nominated Mr. Douglas Hacking, M.P., to be for five years a member of the General Medical Council, in succession to Sir Edward Hilton Young, now Minister of Health.

THE Hunterian Oration of the Royal College of Surgeons of England will be delivered on Monday, Feb. 15th, at 4 P.M., at the College by Mr. Wilfred Trotter. In the evening a dinner will be given by the President and Council of the College.

HOSPITAL GROUNDS AS BIRD SANCTUARY.—The South Staffordshire joint small-pox hospital board has refused to entertain an application for the letting of shooting rights in the grounds of the hospital. The reason given is that, as the result of the scheme of afforestation some years ago, the waste land on which the hospital was originally placed has become a bird sanctuary.

[1] Lymphoid Tissue in the Lung. Its Distribution as Illustrated by a case of "Status Lymphaticus" and its Importance in the Localisation of Inhaled Particulate Matter. By F. W. Simson, M.B., Ch.B. Edin., and A. Sutherland Strachan, M.A., B.Sc., M.D. Glasg. Publications of the South African Institute for Medical Research. 1931.

th large practices in agricultural districts speak of e extreme rareness with which they see cases of ttle ringworm.

Prevention can be largely secured: (1) by issuing structions to farm labourers, &c., as to the infectious ture of the disease; (2) by the provision on the farm suitable places for washing and disinfecting the nds of those who have been in contact with infected ttle; (3) by wearing a washable overall whilst ndling infected cattle and by wearing a washable p whilst milking; (4) by calling attention to the nger of dressing sores, &c., on infected cattle with e naked hands instead of wearing india-rubber oves—which should always be provided and worn r this purpose; (5) by cleansing and lime washing l rubbing-posts, stalls, railings, gate posts, &c., th which it is known that infected cattle have been contact; (6) by preventing children kissing and calves; (7) by ensuring the observance 13, of the Public Health (Meat) Regulations, 24, which prohibits the "blowing" or inflation with e human breath of carcasses of calves slaughtered r human consumption.

The more serious forms of the disease can be revented by advising farm labourers and others apply for medical treatment immediately on the rst evidence of the disease.

My thanks are due to Dr. F. Griffith and Dr. W. M. cott, of the pathological laboratory of the Ministry f Health, for their assistance in preparing the paraaphs dealing with the pathology of the disease.

NORTHAMPTONSHIRE CONVALESCENT HOME.—Mrs. J. G. Shipman has given her late residence, Templemore, Dallington, as a convalescent home for the Manfield Orthopædic Hospital, Northampton, and it has just been handed over. It will be known as the John Greenwood Shipman Home, in memory of the late Dr. Shipman.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENT.)

MILK CONTROL.

DURING the last eight years persistent efforts have been made by the public health service to unify methods and to raise the standards of milk production in the United States. These efforts have both a hygienic and an economic purpose. It has been found that frequent changes in municipal ordinances governing milk-supplies are very expensive to the dairymen, and keep up the price of milk to the consumer. The lack of uniformity in dairy equipment has also increased the price of such equipment to an uneconomic level. A uniform standard approved by high authority is also a great aid to local health officers, many of whom have more training in pharmacology than in the technical aspects of milk *production*.

Within eight years 444 municipalities, embracing a population of some 7½ million people in 25 States have adopted the standard milk ordinance, and are now working under the same system of dairy regulation. In the December number of *Western Hospital Review* Mr. Leslie C. Frank, the sanitary engineer in charge of the Office of Milk Investigation of the Public Health Service, reviews the achievements of this period. He points out that in the seven years 1924–1930 no less than 327 milk-borne outbreaks of communicable disease, 217 of these being outbreaks of typhoid fever, have been reported by State and city health officers. These represent only the outbreaks which have been traced to milk. The fact that the number of such outbreaks does not appear to be diminishing (there were 44 reported in 1930) may perhaps be due to increasing epidemiological skill which is offsetting improved regulation. At any rate the danger of insanitary milk is clearly demonstrated, and Mr. Frank argues that it is best met by the standard milk ordinance on the following grounds:—

The ordinance sets up requirements that guarantee a pure milk-supply. These deal with conditions on the farm as well as with conditions in the pasteurising and distributing plants. It also supplies the health officer with the most powerful available devices for enforcement of the regulations. The grading of milk is regarded as an enforcement device, for it is difficult to sell any milk that is not Grade A in this country. If withdrawal of the Grade A label does not enforce compliance the supply may be barred from the market by revocation of the producer's permit. Penalties are also provided.

What is known as the Public Health Service Milk Code takes up separately each item of the ordinance, explains the reason for it, and describes what may be regarded as the satisfactory limits of compliance. The dairy industry should be given a specified time in which to adjust itself to the new requirements, it being understood that at the end of that time the first announcements of grades will be made. Six months is generally considered to be an ample allowance for this purpose.

"There can no longer be any question," writes Mr. Frank, "but that authoritative and expert opinion is almost unanimously to the effect that all milk should be pasteurised." Tuberculin testing gives almost complete protection against tuberculosis. Stool and urine examinations and Widal tests may eliminate most typhoid carriers from among employees, but no one believes that such tests exclude all carriers.

limited to exposed parts; the hands, wrists, forearms, and upper arms are the parts most commonly affected, since they are those most liable to come into contact with the infected cattle in handling them. The custom amongst farm workers of working during the warm periods of the year with their coats off, and their shirt sleeves rolled up, may also increase the risk of infection. The disease occasionally spreads to parts which are liable to be scratched by the affected hands, such as the head and neck. Occasionally the cheek and forehead are affected through a milk-maid resting her face on the flank of the infected cow whilst milking. The disease may occur around the mouth in children, through kissing and fondling young calves.

The disease may appear as: (1) Rings of inflammation, which may be scaly, vesicular, or pustular. The degree of inflammation varies, but as a rule it is more intense than in lesions due to purely human parasites. (2) Patches or plaques of inflammation which have a rounded or festooned outline. These plaques may be scaly or show vesicles and pustulation.

Persons who have contracted ringworm from cattle are sometimes seriously affected, owing to:—

(*a*) The wide extent of the original infection.

(*b*) A secondary infection of the ringworm patches by septic organisms. This may be facilitated by treatment with drastic local remedies, such as strong cresol preparations, which have been supplied by the neighbouring chemist or veterinary surgeon for use on cattle. The indiscriminate application of these remedies damages the skin, and so provides a suitable habitat for septic organisms.

(*c*) Involvement of the beard region, which may result in inflammation and suppuration of the hair follicles with surrounding infiltration of the skin.

(*d*) Involvement of the scalp, which may result in raised, boggy, phlegmonous swellings with numerous small abscesses, and may lead to inflammation of the glands of the neck.

(*e*) Involvement of the nails, with suppuration; this condition, however, is very rare.

Constitutional disturbance is rare except in cases in which there has been secondary infection by septic organisms; symptoms of septic absorption of varying severity may then occur.

Occasionally the infection in man may assume epidemic proportions. Thus in 1840 most of the inhabitants of the Swiss village, Andelfingen, were reported to be infected with ringworm by sick cattle. During the late war several extensive outbreaks occurred behind the French lines at Verdun, among men tending the large herds of cattle that had been assembled there for feeding the armies.

I am indebted to Captain W. Watt, M.R.C.V.S., of the Ministry of Agriculture and Fisheries, for the following notes on an outbreak of cattle ringworm which occurred at the Cattle-Testing Station at Pirbright in 1925.

The officers and attendants in attendance on the infected cattle were dressed in rubber overalls and sou-wester hats which were sprayed with 1½ per cent. solution of lysol and their hands were washed in this solution on leaving each box. Their hands and faces were washed with carbolic soap before leaving the compound. In spite of these precautions, the following members of the staff became infected.

A veterinary officer cut the point of his chin whilst shaving, and although tinct. iodi fort. was applied the wound began to pour out serum and the tissues began to swell. A second area developed on his chin and was quickly followed by more infected areas. One of the larger areas developed a ring-like appearance and the skin tissues were much thickened. Microscopical examination showed the infecting organism to be a species of *T. ectothrix* and the clinical features of the eruption were such as to make reasonably sure that the infection was with a fungus of animal origin, and not with one of the human varieties, which are in general rather less virulent. Under a simple starch poultice treatment the inflamed tissues gradually became normal but the officer was left with 13 small areas on his face, which are devoid of hair. The duration of the infection was two months.

Four of the attendants were affected. No. 1 was infected on the upper lip, which became more than twice the normal thickness for a time. No. 2 had an infection on the forearm and on the chin. The tissues in both areas were raised up, and had the appearance and colour of an over-ripe strawberry. No. 3 had an area on the back of his hand which poured out serum and developed a crater-like centre. No. 4 had a slight infection of the forearm, which yielded rapidly to treatment.

DIAGNOSIS.

A certain diagnosis of the disease cannot be made without a microscopical examination to demonstrate the presence of the causative fungus, but the large majority of those practitioners interviewed who had seen cases were satisfied that a sufficiently reliable diagnosis could be made from the history and the naked-eye appearances on the following grounds: (*a*) history of prevalence of the disease amongst cattle, or of the coexistence of cases of the disease amongst fellow workers; (*b*) occupation of the patient; (*c*) position of the patches of disease, generally on the hands or arms, a site which is uncommon in other forms of ringworm; (*d*) character of the lesions.

As a matter of fact, the patients usually diagnose the condition for themselves, through their knowledge that cattle affected with the disease are under their care, and that the affected parts are the hands and arms.

Differential diagnosis.—As contrasted with the commoner forms of human ringworm, the lesions of the animal variety affect more particularly the skin, and are peculiarly inflammatory in character; while the fact of contact with cattle obviously affected with ringworm is usually sufficient to settle the animal origin of the lesions. But, if scientific proof were required a complete research would be necessary in each case, establishing on mycological grounds the identity of the fungi cultivated from the human patient with the fungi cultivated from the suspected cattle.

Margarot and Deveze have drawn attention to the fluorescence of hairs infected by ringworm in light filtered through glass containing nickel oxide, known as Wood's glass. They have differentiated between the fluorescence of microsporon and tricophyton infections and state that hairs infected by tricophyton exhibit less fluorescence than those infected by microsporon, but still show a characteristic reaction. More recently Kinnear has reported that only microsporon infections give fluorescence which is entirely absent in tricophyton infections. The great value of these observations in human ringworm of the scalp is in ascertaining the completeness or otherwise of the cure. As neither the diagnosis nor the treatment of cattle ringworm in the human subject presents much difficulty, the method is not likely to be of much practical application in this condition.

PROGNOSIS, TREATMENT, AND PREVENTION.

Prognosis.—Most cases clear up in a few days, often without treatment. Cases, however, occur in which the disease spreads widely and may for weeks prove very resistant to treatment. Suppuration in the scalp or beard may be the cause of inconvenience and suffering for some months.

Treatment.—Most cases are so slight that they are readily cured by home remedies. Treatment by the local application of tincture of iodine or a cresol disinfectant, by the patient himself or by his employer, seems to be so well known and so effective that the large majority of patients do not seek medical advice. This may account for the fact that many doctors

urance providing for domiciliary, investigational,
l pharmaceutical services on the one part, and
isulting and specialist, nursing, and hospital
vices on the other. Besides any capitation fee
d to doctors for any of the above services, the
ient will be required to pay a visitation or service
for each service rendered. It is further proposed
establish funds to provide cash benefits to assist
the payment of consultant and specialist services,
l to assist in the payment of medical and surgical
rsing. Where contributory schemes are initiated
under the control of lay bodies, it is resolved by
: Victorian branch that the medical profession
ill have adequate representation on the executive,
it a proportion of the contributions shall be used
ely for medical benefit, that all benefits shall be
the form of cash benefits to subscribers, and that
ntributors as such shall not be given any direct
presentation upon the executive.

The proposed contribution for nursing and hospital
rvice and consulting and specialist service is 9*d*. per
ek; the cash benefits to subscribers are £2 per
ek for hospital expenses, up to £9 for consultant
d specialist service, £3 3*s*. for confinement, and
1*s*. for an anæsthetic. For domiciliary, investiga-
nal, and pharmaceutical services the weekly con-
ibutions will vary from 5*d*. for single persons under
years to 1*s*. for a subscriber with a wife and more
an two children. The service is to be limited to
ose whose incomes are below £208 per annum for
single man or woman, or £312 for a married man,
ith an additional allowance of £25 for each child.
he service charges are to be 3*s*. 6*d*. for domiciliary
rvice (or other sum agreed upon), 5*s*. for investi-
tional service, or the price of X ray films, and half
e present private prescription rates for pharma-
utical service. It is proposed that the scheme
ould first be tried in a selected district. The
ictorian branch points out that—

> " Hospitals accepting money for services are to contri-
> utors no longer charities, but public utilities. The con-
> ibutor is relieved of indigency and obligation, and offered
> rvice, including medical service, for sixpence a week for
> imself and his dependents. What makes the scheme so
> opular to everybody except the medical profession is that
> e hospitals sell nursing and medical service for sixpence
> week and pay nothing for the medical service. This is
> aid for by (1) the thrifty *independent middle* classes, who
> truggle with higher medical fees, and (ii) by the medical
> rofession."

These schemes are likely to have far-reaching
ffects on the present hospital system in its relation
o the medical profession, and their outcome is
lifficult to conjecture.

RESUSCITATION OF THE APPARENTLY DROWNED.

During the summer months the Australian beaches
re thronged with bathers, and as many as 30 or 40
ersons have been carried out and rescued on one
each in a single day. The number of surf fatalities
s surprisingly small. This is due to a very efficient
rganisation for rescue. Life-saving equipment is
rovided on all beaches, and on many professional
ife-savers are employed. The main credit is, however,
due to voluntary associations, known as life-saving
clubs, whose members are first-class swimmers,
trained in all aspects of surf rescue and resuscitation.
These clubs have houses on all the larger beaches,
and their members form regular patrols. The clubs
are grouped into an association known as the Surf
Life Saving Association of Australia, which is responsible for the *teaching* of the various methods and for
general coördination and control. It issues a handbook, and it has lately been reviewing the methods of resuscitation of the apparently drowned in its local application to the conditions of the Australian surf.

A committee of medical men which has been asked to report has made several important suggestions, and proposes, inter alia, that the treatment of shock be completely revised. It is recognised that resuscitation must take place at the water's edge, and that the patient must not be moved until it is complete. The present teaching is that while resuscitation is proceeding the patient lies on the cold sand in a wet bathing costume until it is finished, when "restoration of the circulation" is carried out by means of vigorous rubbing towards the heart, accompanied by firm slapping of the palms of the hands and the soles of the feet. It is recommended that this rubbing and slapping be entirely discontinued, and that, where assistance is available, the treatment of shock should be begun immediately the patient is brought ashore and whilst resuscitation is proceeding. The measures recommended include drying the patient, laying him on and covering him with a blanket, and the application of warmth.

The method of resuscitation advocated is the Schäfer method with a slight modification. Experimental investigation of pulmonary ventilation during artificial respiration was carried out by Prof. Whitridge Davies at Sydney University to decide a number of doubtful points, and it was found that an excess of ventilation was produced, and that any attempts to produce more ventilation by particular sites for application of the operator's hands or by placing the patient's arms fully extended above his head were unnecessary. The rate recommended was 12 per minute—i.e., five seconds for each complete swing; three forward (expiration) and two back (inspiration). This ratio, which is contrary to normal breathing, was recommended because in artificial respiration expiration is the active movement. Further, investigation of the blood of animals drowned in sea water showed a marked increase in the salinity of the blood of the left ventricle, and a dehydration of the blood.

The modification of the Schäfer method mentioned above refers to the position of the operator in regard to the patient. At present he works from the left side of the patient or astride his body; it is now proposed that he should straddle the patient's left knee between his knees. This gives the greatest ease to the operator, especially to his wrists, which are likely to become very tired.

Consideration is also being given to aspects which particularly affect medical men—e.g., the use of Hewitt's airway and inhalations of oxygen and carbon dioxide during resuscitation, intracardiac injections of adrenalin, and particularly the length of time for which resuscitation should be continued. In regard to this, it is recommended that it should be continued until recovery, or for at least two hours, and only discontinued on the advice of a medical man. Further, all who have been resuscitated must be admitted to hospital, and someone trained in the methods of resuscitation must be present with the patient until such admission takes place.

ENDEMIC TYPHUS FEVER IN AUSTRALIA.

Roughly 300 cases of typhus are known to have occurred in Australia, distributed as follows: Victoria, 1; Queensland, 55; South Australia, 143; Western Australia, 93; Tasmania, nil; New South Wales, 7. Probably many cases have been overlooked, and until the medical profession in Australia consider the possibility of

Expert opinion, however, is divided on the best method of securing pasteurisation. Compulsion, especially in small communities, is often unjust to firms that are too small economically to install the necessary machinery and results in a monopoly of the milk industry by one firm. The health education of the people as well as the local conditions of the industry must determine whether and when pasteurisation shall be made compulsory.

CASUALTIES AT FOOTBALL.

Much discussion has taken place in the press of late regarding the hazards of American football. Deaths from football are not officially notifiable but 40 are known to have occurred during the autumn and winter of 1931. A few of these are attributable only indirectly to the game as that of a boy, aged 16, who was scratched at football and died of septicæmia two weeks later, or another who died about the same time having ruptured his appendix during a game of football and having concealed his injury until the end of the match. Such deaths could result from any form of sport, but the great majority of football deaths are due directly to violence and it is significant that of these 40 deaths only eight were college men, for in college football the greater strength of the combatants is made less dangerous by the greater skill of these highly trained players. It has been said that 40 deaths is not a large number compared with the number of automobile fatalities and this is true. On the other hand insurance companies do not penalise their clients for riding in automobiles, whereas they have of late refused to issue policies against accidental death and injury to football players except at unusually high premiums. Personal experience during four years as a college physician leads me to suspect that the disabling accidents of football are more important than the deaths, but I know of no published figures on this subject.

American football demands from its votaries so many hours of attentive study with a professor of football tactics (called a coach) and such exercise of memory that one marvels that it should be classed as a recreation. Perhaps the coeducational system is a factor in its popularity. For there is no doubt that a good football player exhibits qualities both of strength and of skill that endear him to the other sex. Perhaps, too, these very qualities rank higher in the scale of virtues adopted by a young nation than they do among the more sophisticated nations of Europe.

MEDICAL PRACTICE IN CALIFORNIA.

The latest study published by the Committee on the Costs of Medical Care concerns the medical facilities of San Joaquin County, California. The 100,000 people living in this county spent $3,609,063 on medical care in the year 1929 for the prevention and cure of illness. Physicians received 24 per cent. of this sum, hospitals the same proportion, drug stores (chemist's shops) 19 per cent., and dentists 16 per cent. About 3 per cent. of the total was devoted to public health activities. Of the 79 practising physicians, 14 are specialists, 18 are "partial specialists," and 47 are general practitioners. The specialists work 40 hours per week, the partial specialists 48 hours, and the general practitioners 57 hours. The median numbers of patients treated are respectively 900 for the specialist, 1475 for the partial specialist, and 800 for the general practitioner. The median net income for all physicians is $5455. The net incomes vary from a loss of $256 to an income of over $30,000. Seven osteopaths made an average net income of $5121, 14 chiropractors an average of $2781, 17 Christian Science practitioners an average of $1882.

AUSTRALASIA.

(FROM OUR OWN CORRESPONDENT.)

CONTRIBUTORY SCHEMES AND THE MEDICAL PROFESSION.

I HAVE previously referred to the crisis in the finances of the hospitals in Australia and some of the means adopted to relieve it. Most of the hospitals are largely dependent on government aid for their upkeep, and each State has taken different steps to meet the position. Thus in Western Australia a special hospital tax has been imposed, while New South Wales and Queensland have instituted Government lotteries.

New South Wales has now started a scheme of voluntary contributions which has given much concern to all medical practitioners of the State. It is not industrial, but is intended for the whole community, and people of every financial status are invited to participate. It is expected ultimately to absorb all existing schemes, but is otherwise not intended to interfere with the ordinary sources of revenue of the participating hospitals.

By a system of regular contributions of 6*d*. per week from every person willing to join, it is hoped to provide a regular volume of income. The main benefits are as follows:—

1. Contributors, who by reason of their financial circumstances are eligible for admission to a public hospital and are medically certified as requiring indoor accommodation in an acute hospital, shall not be required to make any payments to the hospital towards the cost of hospitalisation of themselves or their dependents, and shall not be required to pay any medical fees.

2. Other contributors will be given credit of 7*s*. per diem off the cost of accommodation for private or intermediate patients as the case may be, and shall only be required to pay the hospital the difference between 7*s*. per diem and the charges fixed for private or intermediate accommodation and medical fees as laid down.

Contributors and their dependents will be entitled to the benefits for a period of 12 weeks in any 12 months. X ray and other scientific services will be available free of charge to persons eligible for public ward accommodation, and for others at certain charges to the hospital, to be determined, together with the fees of the radiologist, pathologist, and so on. It is also proposed to establish a special fund for the purpose of supplying destitute persons, whether members of the fund or not, with artificial limbs, spectacles, and special appliances for the sole use of the patient.

The opinion of the profession in Sydney on this scheme is probably best expressed in resolutions which were passed at a meeting of the British Medical Association on Oct. 30th, in which it was agreed that any contributory scheme, industrial or otherwise, providing for out-patient services to the contributor is not acceptable. Further, the medical profession, whilst affirming its traditional principle of free treatment for the indigent sick, insists that its interests be conserved in regard to the other classes of the community by payment for services rendered. The profession is prepared to support the scheme, provided proper arrangements are made to safeguard the interests of medical practitioners in regard to intermediate and private patients.

The B.M.A. in Victoria has also had a scheme under consideration. It is a proposal for voluntary surance providing for domiciliary, investigational, and pharmaceutical services on the one part, and consulting and specialist, nursing, and hospital services on the other. Besides any capitation fee paid to doctors for any of the above services, the patient will be required to pay a visitation or service fee for each service rendered. It is further proposed to establish funds to provide cash benefits to assist in the payment of consultant and specialist services, and to assist in the payment of medical and surgical nursing. Where contributory schemes are initiated or under the control of lay bodies, it is resolved by the Victorian branch that the medical profession shall have adequate representation on the executive, that a proportion of the contributions shall be used solely for medical benefit, that all benefits shall be in the form of cash benefits to subscribers, and that contributors as such shall not be given any direct representation upon the executive.

The proposed contribution for nursing and hospital service and consulting and specialist service is 9*d*. per week; the cash benefits to subscribers are £2 per week for hospital expenses, up to £9 for consultant and specialist service, £3 3*s*. for confinement, and £1 1*s*. for an anæsthetic. For domiciliary, investigational, and pharmaceutical services the weekly contributions will vary from 5*d*. for single persons under 21 years to 1*s*. for a subscriber with a wife and more than two children. The service is to be limited to those whose incomes are below £208 per annum for a single man or woman, or £312 for a married man, with an additional allowance of £25 for each child. The service charges are to be 3*s*. 6*d*. for domiciliary service (or other sum agreed upon), 5*s*. for investigational service, or the price of X ray films, and half the present private prescription rates for pharmaceutical service. It is proposed that the scheme should first be tried in a selected district. The Victorian branch points out that—

> "Hospitals accepting money for services are to contributors no longer charities, but public utilities. The contributor is relieved of indigency and obligation. and offered service, including medical service, for sixpence a week for himself and his dependents. What makes the scheme so popular to everybody except the medical profession is that the hospitals sell nursing and medical service for sixpence a week and pay nothing for the medical service. This is paid for by (i) the thrifty independent middle classes, who struggle with higher medical fees, and (ii) by the medical profession."

These schemes are likely to have far-reaching effects on the present hospital system in its relation to the medical profession, and their outcome is difficult to conjecture.

RESUSCITATION OF THE APPARENTLY DROWNED.

During the summer months the Australian beaches are thronged with bathers, and as many as 30 or 40 persons have been carried out and rescued on one beach in a single day. The number of surf fatalities is surprisingly small. This is due to a very efficient organisation for rescue. Life-saving equipment is provided on all beaches, and on many professional life-savers are employed. The main credit is. however, due to voluntary associations, known as life-saving clubs, whose members are first-class swimmers, trained in all aspects of surf rescue and resuscitation. These clubs have houses on all the larger beaches. and their members form regular patrols. The clubs are grouped into an association known as the Surf Life Saving Association of Australia, which is responsible for the teaching of the various methods and for general coördination and control. It issues a handbook, and it has lately been reviewing the methods of resuscitation of the apparently drowned in its local application to the conditions of the Australian surf.

Further, all who have been resuscitated must be admitted to hospital, and someone trained in the methods of resuscitation must be present with the patient until such admission takes place.

ENDEMIC TYPHUS FEVER IN AUSTRALIA.

Roughly 300 cases of typhus are known to have occurred in Australia, distributed as follows: Victoria, 1; Queensland, 55; South Australia, 143; Western Australia, 93; Tasmania, nil; New South Wales, 7. Probably many cases have been overlooked, and until the medical profession in Australia consider the possibility of this disease in all anomalous

lous cases, diagnosed as measles, typhoid fever, &c., it will not be possible to form any accurate idea of the incidence. It has only been known in New South Wales since 1927. The disease appears to be more common in males than females, particularly between the ages of 31 and 40 years, and during the winter months. The association of the prevalence of rats and mice has been particularly investigated, and, in South Australia, it has been thought that its incidence coincided to some extent with the demolition of buildings and consequent spread of rats. The tropical rate mite (*Liponyssus bacoti*), whose bite, it has been suggested, spreads the disease from infected mice, is known to occur in Australia, and, in fact, was first reported as a blood-sucker of man at Sydney by Hirst.[1]

THE LÜBECK TRIAL.

(FROM OUR BERLIN CORRESPONDENT.)

(*Continued from 1931, ii., 1429.*)

THE question whether B C G may in certain circumstances become virulent, which is of great importance to the accused, has been fully debated by numerous medical experts. The court thus has more and more become a medical forum, the presiding judge seldom interfering with the discussions of the experts, because he is anxious to avoid a possible quashing of the verdict by the High Court of Leipzig, which would mean a repetition of the whole trial.

Prof. Hans Much, of Hamburg, said that there are stocks of B C G which are innocuous, and others which may become virulent. He mentioned a report received by him from Bulgaria where there had been an accident similar to the one in Lubeck. Asked by the public prosecutor whether the B C G might have become virulent by cultivation on an albuminous medium with hæmatin, he answered that according to Petroff's view this might happen. Prof. Martin Hahn, director of the Hygienic Institute of Berlin University, said that Prof. Deycke had taken a great risk by producing B C G on an albuminous medium. It was unnecessary to have produced the vaccine in Lübeck at all, when it could have been purchased from the Robert Koch Institute in Berlin, or from the Pasteur Institute, which is prepared to send cultures and even emulsions abroad to places further away than Lubeck. Prof. Uhlenhut, of Freiburg, said that the efficacy of the Calmette method has not yet been proved. With Prof. Sesiffert he had in a single instance found, like Petroff, dissociation of the B C G into three different species. One of these was very virulent, and guinea-pigs vaccinated with it developed tuberculosis. If B C G may under certain conditions cause tuberculosis in guinea-pigs it is wrong, he said, to give it to patients without a previous test on animals. In Lubeck, however, something particular must have happened to cause so high a mortality: either the primary culture was virulent, or it was contaminated or exchanged. He was of opinion that there should have been a special laboratory for the production of the vaccine. The work done in Lübeck was done without enough care and without the sense of responsibility required when producing a vaccine for human beings.

Prof. Wilhelm Kolle, of Frankfurt, did not agree with Prof. Uhlenhut about Petroff's experiments. They had, he said, been repeated at the Robert Koch Institute, at the German Health Office, at the Pasteur Institute, and at his own institute for experimental therapy, and the results were always negative. He believed the disaster was due to mixing of the B C G cultures with the stock of bacilli from the Kiel laboratory. Sister cultures of the original B C G sent to Lubeck had been sent to Riga and to some places in France without doing any damage to the thousands of children vaccinated with them. Prof Deycke then reported that he had made experiments on himself to ascertain whether the Kiel culture and the cultures obtained from organs of dead Lübeck infants were the same or different. He found that the cutaneous reaction produced by the Kiel culture was much stronger than that produced by the Lübeck culture. He showed photographs in which the different degree of reaction could be seen. Prof. Ludwig Lange, of Berlin, said that a cutaneous reaction was inadequate evidence. The original Kiel culture had certainly been altered by passage through the bodies of the infants.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

HONORARY FELLOWSHIPS.

AT their meeting on Jan. 1st, 1932, the President and Fellows of the Royal College of Physicians of Ireland elected two honorary Fellows, Sir Almroth Wright, F.R.S., and Mr. Edward Francis Stephenson. Sir Almroth Wright is, of course, an Irishman, and received his medical education at Trinity College, Dublin, whence he graduated M.B. in 1883. Among the honorary degrees and diplomas that he already possesses are the D.Sc. of Dublin University, and honorary Fellowship of both Trinity College and the Royal College of Surgeons in Ireland. Dr. Stephenson is himself a licentiate of the College which now grants him an honorary Fellowship, and is a Fellow of the Royal College of Surgeons in Ireland. His early professional work was as dispensary doctor in Dunmore, County Waterford, until some 20 years ago he was appointed a medical inspector of the Local Government Board of Ireland. In 1919 he became an acting commissioner and member of the Board, and after the change of government he was chief medical adviser of the Department of Local Government and Public Health. In that capacity he has had a great responsibility in the reorganisation of the medical services of the country, and in the development of public health work which has taken place in the last few years. The compliment paid him by the Royal College of Physicians may be regarded as a recognition both of the value of his public constructive work and of the esteem in which he is held as a just and capable administrator.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Owing to financial pressure it has been decided by the board of management of this hospital that, as a temporary expedient, a registration fee of 6*d.* be charged to all new out-patients and 1*s.* to all new cases referred to the massage and electrical departments and to the X *ray department*; that medicine be supplied at the rate of 3*d.* for one week's prescription and 6*d.* for two or more weeks; that the maintenance charge for paying patients admitted on the lower scale be raised from 1½ to 2 guineas a week, and that all patients, except such as were admitted under contract, be asked to make a voluntary contribution towards their maintenance of not less than 2*s.* a day. Necessitous cases will always be treated free. It was roughly estimated that there would be a deficit on the year's working of nearly £8000. and an accumulated deficit on the general fund of £17,500.

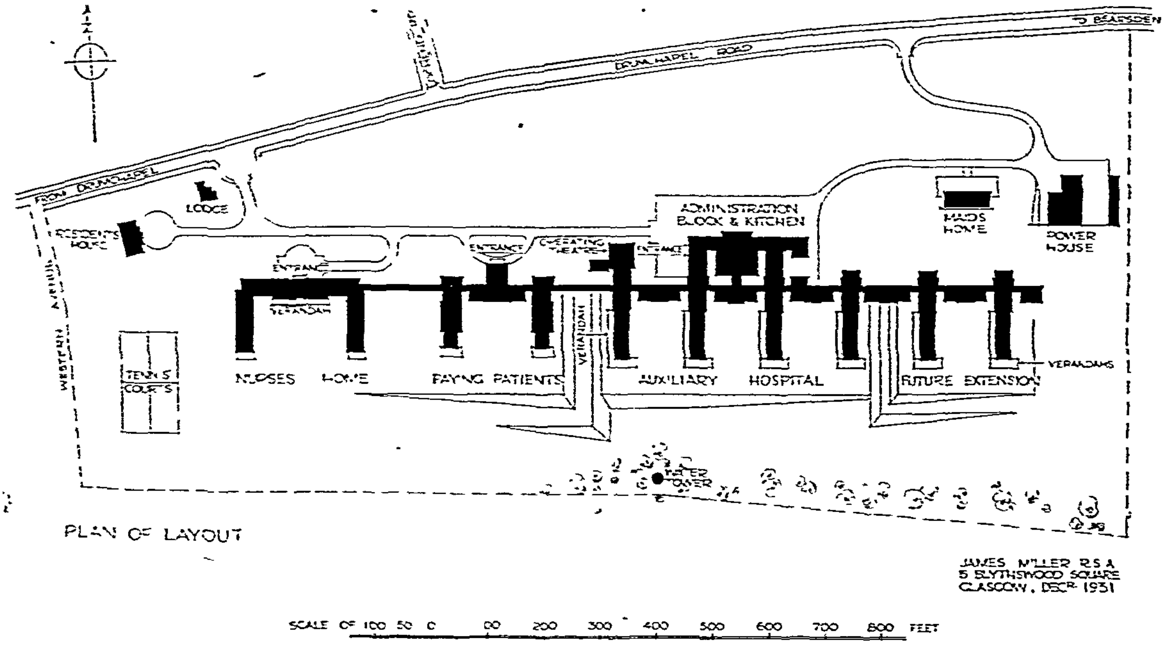
---

[1] Bull. Entom. Res., 1914, v., 225.

GLASGOW'S NEW HOSPITAL.

(FROM OUR CORRESPONDENT IN SCOTLAND.)

At a time when many people shake their heads bout the future of the voluntary hospital movement, is gratifying to find that the managers of the lasgow Royal Infirmary have taken a great new ep. They have decided to provide a "pay" ospital for patients of moderate means, and a ursing home on the same site. Ultimately, these ew institutions will accommodate 368 patients in the uxiliary hospital and 120 in the nursing home, a tal of 488. This step forward has been made ossible by two things: first, the enterprise of r. James Macfarlane, LL.D., chairman of the Royal nfirmary, who several years ago saw the need for this evelopment and received contributions from many terested people towards it; second, a gift from Dr. Macfarlane and his brother of the additional site of 16 acres, making 32 acres in all, free of all burdens.



Royal Infirmary Auxiliary Hospital and Nursing Home, Canniesburn.

The architect, Mr. James Miller, F.R.I.B.A., of Glasgow, has provided the accompanying plan, which shows that the auxiliary hospital consists of six ward blocks, all placed on the south side of the main corridor. In addition to the large wards, which have 120 beds each, two small wards of four beds each are attached to each ward unit.

These smaller wards are placed on the south side of the main connecting corridor, with a large day-room for patients placed between. This arrangement allows these wards and day-room to have a southern aspect with an uninterrupted view of the grounds. Their windows, which will be of the sliding type, occupy the entire length of the room, and can be thrown completely open, transforming these apartments into large open balconies, so to speak, in fine weather. The above arrangement has the further advantage of reducing the length of the projecting main ward blocks, and, as the latter are spaced with ample space between, the depressing effect of the narrow and deep blind alleyways formed by the ward blocks, as found in many hospitals, is avoided. A new feature of the large wards is that the sanitary block is placed at the entrance end of the wards instead of at the extreme end, an open verandah taking the place of the sanitary block at the south end of each ward.

On the west side of all the main wards continuous verandahs are arranged with every alternate window in the ward formed as a French casement, so that beds can be wheeled on to the verandah. The side verandahs combined with the verandahs at the ends of the wards will be capable of accommodating the whole of the 20 beds in each ward. Instead of being placed at right angles to the walls the beds are placed parallel to the side walls, and each group of four beds is separated from the remainder by means of glazed screens of enamelled steel 7 ft. high. Every ward in the hospital and nursing home is planned with its main axis running north and south, thereby ensuring the maximum of sunlight.

The administration block is placed to the north side of, and central to, the ward section of the hospital. Advantage has been taken of the levels of the ground to place this block one storey below the ground floor of the main ward blocks, while a main service corridor on the same level as the administration block and connecting with it, links up all the ward units in the auxiliary hospital as well as the nursing home and the nurses' home, an arrangement which has the advantage of preventing general traffic passing through or near the ward units.

The nursing home is placed to the west of the auxiliary hospital, and provides for 120 patients. The majority of the beds in this block are in single wards, while there are four wards containing four beds each.

The nurses' home is to the west of the nursing home and accommodates 128 nurses. A connecting corridor links up the home with all sections of the scheme.

The plan represents the complete scheme, and at present it is proposed to proceed only with the first section. No public appeal for funds has been made, and the sum available is only £75,000. But as the site is free, the managers propose to make a start by applying these funds for the purposes for which they were intended.

MEDICINE AND THE LAW.

"B.P." as a Description of Drugs.

It is reasonable to say that to doctors and chemists the letters "B.P." indicate the British Pharmacopœia; when applied to medicinal preparations, they probably convey the same significance to members of the public. If private firms seek to market such preparations bearing the letters "B.P." as a trade description, there is obviously a risk of confusion and misunderstanding. The General Medical Council, which has statutory responsibilities of a national kind with respect to the British Pharmacopœia, has felt obliged to bring an action (reported in the *Pharmaceutical Journal* for Dec. 26th) against Barrett Proprietaries Ltd., manufacturing chemists of Blackburn, who have been using the letters "B.P." in marketing their goods. It is true that the Council is not a commercial undertaking financially affected by the sales of competing commercial undertakings; its functions are limited to publishing the list of standard drugs. Nevertheless, when it applied to Mr. Justice Clauson just before Christmas for an injunction against Barrett Proprietaries, it could reasonably protest that this marking of the defendant's goods was calculated to lead purchasers to suppose that the goods were of British Pharmacopœia standard. If the public were thus deceived, the reputation of the Council might suffer. Some of the Barrett preparations (for instance, stomach and indigestion mixture) were articles which would never be included in the British Pharmacopœia; the public must not be allowed to suppose that the Council was exceeding its proper functions and launching forth into the prescription or recommendation of stomach and indigestion mixtures. Attention was drawn to the fact that Mr. Barrett, the head of the defendant firm, had chosen the suffix "Proprietaries" though no proprietary rights were claimed for his preparations; had he done this in order to give some colour of right to the use of the letters "B.P."? On the other hand the defendants offered evidence that Mr. Barrett had been in the drug trade all his life, that he adopted the word "Proprietaries" because the company intended some day to sell proprietary preparations, that the company's goods thus marked had been on sale for some months, that the marking could not be changed without great expense, and that neither chemists nor anybody else would connect the Barrett "B.P." with the British Pharmacopœia.

At this stage the proceedings were in the form of an *ex parte* motion for an injunction. An injunction cannot be granted unless the party claiming it has sufficient interest in the relief claimed. The learned judge found himself unable to grant the injunction, apparently through doubt whether the Council could show pecuniary damage. The case will now proceed so that evidence may be heard on both sides. The judge's comments seem to show that the action initiated by the Council was not unjustified. Without anticipating the ultimate decision, he did not disguise his first impressions. He expressed surprise that honest traders, intending honestly to carry on business as sellers of drugs, should ask him to believe that they did not realise that this prominent use of the letters "B.P." would imply connexion with the British Pharmacopœia. Though the defendant company said it had incurred great expense in marketing its goods in this way, he would have been glad if they had asked for an opportunity of revising a method of trade which would hardly commend itself to high-minded traders.

NEW YEAR HONOURS.

The list of honours issued on Jan. 1st contains the names of the following members of the medical and dental profession:—

Privy Councillor.

Major Walter Elliot Elliot, *M.C.*, M.B., M.P.
Financial Secretary to the Treasury.

K.C.S.I.

Major-General Sir Leonard Rogers, C.I.E., F.R.S., I.M.S., retd.
President of the India Office Medical Board.

K.C.M.G.

Sir James Kingston Fowler, K.C.V.O., C.M.G.
Member of the Colonial Advisory Medical Board.

K.C.V.O.

John Weir, C.V.O., M.B.
Physician-in-ordinary to the Prince of Wales.

K.B.E.

Frederick Norton Kay Menzies, M.D.
Medical officer of health and school medical officer, London County Council.

Augustus Moore Daniel, M.B.
Director of the National Gallery.

D.B.E.

Miss Edith Mary Brown, L.R.C.P.
Principal of the Women's Hospital and Christian Medical College, Ludhiana, Punjab.

Knights Bachelor.

George Buckston Browne, F.R.C.S.

Henry Hallett Dale, C.B.E., M.D., Sec. R.S.
Director-in-chief of the National Institute for Medic[illegible] Research.

C.S.I.

Colonel John Philip Cameron, C.I.E., I.M.S.
Late Inspector-General of Prisons, Madras.

C.I.E.

Lieut.-Colonel John Morison, M.B., I.M.S.
Director of King Edward VII. Pasteur Institute and Medical Research Institute, Shillong, Assam.

C.V.O.

Marcus Antonius de Lavis-Trafford, M.V.O., O.B.E., M.D.
Physician-in-ordinary to the Duke of Connaught.

C.B.E.

Major Thomas John Hallinan, O.B.E., M.B.
Inspector-General of Health Services, Iraq.

O.B.E. (Military).

Surgeon Lieut.-Commander Andrew Lawrey, L.D.S.

O.B.E. (Civil).

Stanley Desmond Rieley, M.R.C.S.
Superintendent of Central Jail, Mach, Baluchistan.

Francis Alexander Innes, M.B., W.A.M.S.
Medical officer of health for Gambia.

Kaisar-i-Hind Medal.

William Nunan, M.D.
Police surgeon, and professor of medical jurisprudence at the Grant Medical College, Bombay.

PUBLIC HEALTH SERVICES

NNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

HE following are 1930 statistics of Belfast, vcastle-upon-Tyne, and Cardiff.

Name of strict and stimated (R.-G.) nid-year pulation.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality in childbirth.

diff .. .. (223,900)	16·9	11·4	1·15	1·34	1·4	2·1	72/36	22	5·3

Notified stillbirths per 100 live births: Belfast, 4·7. Registered stillbirths per 100 live births: Newcastle-uponne, 4·3; Cardiff, 4·9.

Belfast.

Dr. Charles S. Thomson records progress in aternity and child welfare work. The weekly ssions are to be increased from 6 to 19, 6 to be for itenatal work and 13 for infant consultations. ıe increase of the health visitors from 11 to 20 will able attention to be given to the pre-school child. Midwives are at present suspended for the purpose disinfection when any cases of puerperal pyrexia cur, and provision is needed for compensation in ich cases. The Nursing Home Act came into force January, 1930, and during the year 53 applications ere received, of which nine were refused.

About 8 per cent. of the milk samples are found to ontain tubercle bacilli, and Dr. Thomson advocates iat the municipality should only allow Grade A (T.T.) nd pasteurised milk to be supplied to infants and iothers under their scheme. A curious point has risen with regard to the notification of pulmonary iberculosis. Only those cases are notifiable in which here is "positive" sputum.

Dr. Andrew Trimble, tuberculosis officer, points ut that under the new regulations for insured ersons, which came into force on Oct. 1st, 1930, the anel doctor is instructed to report "suspected" ases of tuberculosis. But Dr. P. S. Walker, nedical superintendent of the sanatorium, points ut that the type of case admitted is even more dvanced than in previous years and that the anatorium is not equipped structurally or otherwise or advanced cases, although quite satisfactory as a anatorium. He points out that albumose or albumin s generally present in a positive sputum. It was only absent in nine out of 178 in recent examinations. He thinks that the presence of albumin in a negative sputum should be regarded as a reason for frequent examinations. He gives some interesting particulars with regard to pregnancy and tuberculosis. Out of 1113 pregnancies of tuberculous mothers, 63 ended in miscarriage, 17 in stillbirths, 13 in premature births, and 1020 in living full-term children. Of 1397 tuberculous mothers, 342 improved during pregnancy, 725 were in statu quo, 271 were in worse health, and 50 died within a year of delivery. The infant mortality-rate of 926 children born of 410 tuberculous mothers during seven years was 93, as compared with 102 for the general population. This agrees with the results obtained in Lancashire and Leeds, and may be due to the more careful supervision of these mothers.

The corporation pays £1000 annually to the maternity hospital (27 beds). A new maternity hospital, with 100 beds, is approaching completion within the grounds of the Royal Victoria Hospital. The Belfast Nursing Association employs 11 nurses for district work and receives no subsidy from the corporation. Dr. Thomson advocates an arrangement being made for the home nursing of measles and whooping cough by these district nurses.

There is great need of a large number of houses for the working classes. No fewer than 146 streets involving 3176 houses are known to the health department as requiring drastic treatment, and many new houses are required for these tenants. They are usually not in a position to pay the rent of the modern house, so that it is absolutely necessary to provide "kitchen" houses at low rents.

There are no private slaughter-houses in Belfast and over 5000 animals are slaughtered every fortnight at the municipal abattoir. A by-law for the compulsory use of the humane killer came into operation on March 19th, 1930.

Newcastle-upon-Tyne.

Dr. Harold Kerr says the hours of sunshine at Armstrong College were 1076, as against 1211 for the previous year, whilst near Morpeth the hours were 1323, as compared with 1566 in 1929. The city had therefore only three-quarters of the sunshine available for the neighbourhood. The regional committee for dealing with the smoke of Tyneside is without hope at present. The various gauges showed some improvement, probably owing to industrial depression. The citizens look forward to the advent of the "grid" and the abolition of the electric power station, with its three-fold deposit of ash. Smokeless fuel makes slow progress and Dr. Kerr and some medical confrères set an example by using gas-coke lit by gas burners, with a 10 per cent. advantage to their pockets.

As the result of the Local Government Act, 1929, the health committee took control of the poor-law infirmary, now called the Newcastle General Hospital; of the domiciliary medical service; of the care of boarded-out children; of poor children under 5 years; and of public vaccination. Progress has been made in the appointment of the new staff for the General Hospital and the redistribution of beds. Advanced pulmonary tuberculosis has been transferred to Walker Gate isolation hospital, for which a new pavilion will be needed. The top floor of the new block at the general hospital has been reserved for surgical cases of tuberculosis (72 beds). Already there is a shortage of beds at the general hospital and 200 more are needed. The public assistance committee controls the neighbouring institution and may remove elsewhere, thus releasing the institution for the use of the general hospital. Close coöperation is being maintained with the voluntary hospitals. The domiciliary medical service is likely to be converted to an open panel system, the patients to have their own choice of attendant and the health committee to be responsible for the dispensing of medicines. This system will be tried in about half the city, where there are vacancies at present and, if successful, will be applied to the rest of the town.

Diphtheria had again a low incidence. 200 cases with a case-fatality of 2·0 per cent., as compared with 259 in the previous year with a case-fatality of 5·4 per cent. Six Newcastle residents were affected by typhoid fever and 37 by paratyphoid B. Of 30 cases discovered in July and August, 21 had the same milk-supply. One carrier was found at the dairy but no suspicious circumstance at the supplying farms. The suspected milk was subjected to pasteurisation and subsequently the dairy has been registered for milk pasteurised according to the regulations. Dysentery was discovered in 87 persons, five of whom died. Two small outbreaks occurred in a children's ward of the general hospital, each caused by a different type of bacillus. Antitoxin was used for 43 per cent. of the scarlet fever cases admitted to hospital, and is thought to reduce the cases requiring operation by the oto-rhinologist. There were 82 notifications of ophthalmia neonatorum, three of which resulted in slightly defected vision. Owing to the development of tuberculosis in a member of the Walker Gate staff, radiographic records are now taken of every nurse and maid employed, as a measure of protection both to the staff and to the committee.

The three new infant welfare centres have supplied a great need in the newer housing areas. Owing to a difficulty in securing health visitors a training course has been established in the health department. These subsidised pupils undertake to do their training, sit for examination, and remain for six months afterwards as health visitors. The successful ones have filled all the vacancies on the staff. The infant welfare and school medical services have been linked up and the records of the former are passed on with the school entrant.

Considerable alleviation of overcrowding is taking place. Since the war the housing committee has completed 5549 houses, as against 3297 by private enterprise. At the end of 1930 there were 1059 municipal houses in course of erection and provision has been made in the latest schemes for a small proportion of two-roomed houses for aged persons. The Act of 1930 has greatly facilitated progress with insanitary areas. The tenement by-laws are being vigorously enforced and the institution of proceedings in 88 cases, as compared with 198 in the previous year, indicates more compliance on the part of owners. During 1930 caravans were reduced in number from 22 to 5. All the eight swimming baths have been equipped with a continuous system of filtration and aeration. The kata-thermometer is used for testing the ventilation of cinemas and theatres. The standard adopted is that the cooling power should not be below six by the dry, nor below 18 by the wet kata-thermometer. Of the buildings tested 28 proved first-class and eight second-class.

Cardiff.

Dr. R. M. F. Picken says the health of Cardiff does not appear to be materially affected by the trade depression of the last ten years. Some significance may be attached to the greater proportion of school-children found to be suffering from defects and to an increase in ailments found among expectant, parturient, and nursing mothers at the clinics. It is satisfactory, he says, that tuberculosis—that sure measure of extreme hardship—shows no upward tendency. The absence of gross deficiency is a tribute to the efficiency of the various methods of public assistance.

On April 1st the city council took over the work of the poor-law authority, whose area extended beyond the city boundaries. The poor-law institutions were transferred on the understanding that a proportion of the accommodation would be available for the county. The hospitals were not separate from the institutions, but their control has been unified by the appointment of the medical officer of health as medical officer for public assistance. On the other hand, Llandough hospital (340 beds), which was in course of construction by the guardians, has been allocated to the health committee as a general hospital.

Diphtheria continued to be prevalent. The notified cases were 731, as compared with 735 in the previous year; and the case-mortality was 3·97 per cent. Owing to this increased prevalence a special effort was made to immunise as many children as possible during the summer, a medical officer, a nurse, and two clerks being told off for the campaign. Over 4000 children were immunised, at a cost of *3s. 7½d.* per child. A table is given, showing the percentage of children at each age-period, who are presumed to be immune, in order to arrive at some measure of the influence of this effort upon the incidence of diphtheria in 1931 and subsequent years. Among the 42 notified cases of ophthalmia neonatorum no damage to eyesight was reported. The arrangement in 1929 made for the home nursing of pneumonia by the Queen's nurses was continued and 66 cases were referred to them during the year. Out of 322 cases of scarlet fever admitted to hospital, 52 received injections of scarlet fever antitoxin. The hospital mortality among 92 cases of measles was 5·4 per cent.

Dr. C. J. McSweeney gives an account of the work of the Lord Pontypridd Hospital, reserved for the treatment of children suffering from early rheumatism, which deserves wide publicity. The children admitted numbered 115, varying in age from 5 years to 14. An effort is made to exclude children with established heart disease, but in some cases valvular disease may have developed during the wait for beds, and it is the practice also to give the child the benefit of the doubt. During the year five children, classified on admission as having established valvular disease, lost all signs of it, whilst four others were regarded on discharge as presenting only minor cardiac manifestations. Among 100 cases treated to a conclusion in 1930 the proportion of normal hearts was raised from 15 to 60. The recovery-rate would have been higher still if every case of active carditis could have been admitted immediately on ascertainment. On two years' experience Dr. McSweeney estimates that 35 beds would be a reasonable provision instead of the 24 available. It was possible to obtain a reliable family history in 98 instances and in the case of 44 of these a history of juvenile rheumatism in a parent was unequivocal; and among these 98 children, 28 had one or more brothers or sisters afflicted with definite juvenile rheumatism. Generally speaking, Dr. McSweeney says, recurrences have been slight and brief, but it is, of course, far too early to express a definite opinion as to the permanency of results.

To prevent risk of urticaria to bathers (THE LANCET, 1930, ii., 752), Roath Park Lake was treated in March, when a third full, with a solution of 1 in 500,000 of copper sulphate. Towards the end of June the cercariæ were becoming numerous in the water-snails examined and there were a few complaints of skin eruption. The lake was again treated and bathing proceeded until the end of the season without further complaints. A case of lead-poisoning attributed to cider, drawn from a cask through a lead pipe, has come to the notice of the Welsh Board of Health, and Mr. S. Dixon, the public analyst, has made appropriate recommendations.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 26TH, 1931.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 32 (last week 44); scarlet fever, 1303; diphtheria, 744; enteric fever, 36; pneumonia, 1180; puerperal fever, 33; puerperal pyrexia, 69; cerebro-spinal fever, 29; acute poliomyelitis, 7; acute polio-encephalitis, 2; encephalitis lethargica, 10; dysentery, 28; ophthalmia neonatorum, 61. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Dec. 29th–30th was as follows: Small-pox, 75 under treatment, 1 under observation (last week 80 and 0 respectively); scarlet fever, 1401; diphtheria, 1499; enteric fever, 9; measles, 597; whooping cough, 435; puerperal fever, 18 (plus 11 babies); encephalitis lethargica, 223; poliomyelitis, 3; "other diseases," 240

CORRESPONDENCE

ESEARCH IN ASTHMA: THE URINARY PROTEOSE.

To the Editor of THE LANCET.

R,—In a letter published in your columns on , 5th, 1931, Dr. G. H. Oriel made reference to e work recently carried out at the Asthma Clinic, 's Hospital, using a "proteose" prepared by from the urine of a patient with hay-fever ma. At the outset of the work in question I, onally, was quite as sceptical regarding the ns made for this preparation as Dr. Freeman ld still appear to remain. Positive erythema wheal reactions were, however, obtained and rded by slide tracings in the high proportion of s indicated. The only conclusion appeared to that the urine in question contained antigens t least haptene substances derived in some manner n the pollen protein which caused the patient's icks.

he presence of such derivatives in the urine of viduals with marked states of protein hyper- sitiveness is not unlikely, in view of the conclusive nonstration by "precipitin" tests that skin cting substances are excreted in the urine during ere reactions to bacterial infection, notably by pneumococcus.[1] It is to be hoped that eventually lence other than that provided by the skin test l enable a definite decision to be reached in the non- terial cases.

he production of an ether-urine emulsion which ms the first stage of Dr. Oriel's procedure in the paration of his rather ill-termed "proteose" ears to involve the concentration at the emulsion erfaces of every substance which happens to be sent in urine in a colloidal form. Subsequent atment of the viscid emulsion layer with alcohol ves to precipitate such substances as have collected the interface in an aggregated form, suitable for ther extraction and purification, but may also olve partial or complete denaturation of any tein matter present, while leaving comparatively affected the simpler haptene substances known to be rived from bacterial breakdown.

It is not surprising therefore that, quite apart from e dermatological considerations raised by Dr. H. W. Barber, the skin test demonstration with this urinary colloidal material very frequently fails in those cases of hypersensitiveness which appear to be associated with inhaled or ingested protein.

I am, Sir, yours faithfully,

E. T. CONYBEARE.

Osler Medical Clinic, Johns Hopkins Hospital,
Baltimore, Maryland, Dec. 21st, 1931.

PROTEIN IN ASTHMA.

To the Editor of THE LANCET.

SIR,—Dr. Behrman has pointed out (Dec. 26th, p. 1433) an apparent omission in the paper by Dr. Porter and myself which possibly we should have explained in the original. It is, however, impossible to include notes of all precautions taken without the risk of becoming tedious. We considered this question very carefully and decided that the cases themselves formed their own controls. For we could not produce any effect on a given case until we struck the right dose for that case. Also, I would point out that the type of case dealt with is more or less immune to psychological effect of a "new" treatment. They, poor things, have had so many without result. And we were careful *not* to give any suggestion of a marvellous cure. Further, although I must agree that, especially in a mild asthmatic, there *may* be a nervous factor usually associated with the time of onset of attack, the allergic state in an advanced asthmatic is in no way dependent on the nervous system.

But I may take this opportunity of mentioning to Dr. Behrman and others that one of my assistants has obtained a mild effect with proteins in epilepsy. *Not* a marked effect. And I should be grateful if someone in touch with a larger number of epileptics would make some attempt further to study this effect. Apparently the dose is considerably higher than in asthma.

Dr. Porter has not seen this letter for he is out of England. I am, Sir, yours faithfully,

THOMAS NELSON.

Grosvenor-street, Mayfair, W., Dec. 30th, 1931.

A NEW METHOD OF APPROACH TO THE SEMILUNAR CARTILAGES OF THE KNEE-JOINT.

To the Editor of THE LANCET.

SIR,—Mr. Timbrell Fisher's choice of this title for his note on the combined anterior and posterior approach to the semilunar cartilages (THE LANCET, Dec. 26th, 1931) is not fortunate, for the procedure is familiar to most orthopædic surgeons in this country; thus, amongst others, I myself have practised an identical technique for the past eight years in exceptional cases of cartilage injury. It is true that little has been written on the combined approach, but if any name, or combination of names, is to be attached in future to this operation, that of the late Alwyn Smith of Cardiff must come first. Alwyn Smith's advocacy of the combined approach can be found in the Journal of Bone and Joint Surgery (April 1925), and again in his contribution to the Robert Jones Birthday Volume (Oxford University Press, 1928), an essay written with indomitable courage during the long crippling illness which carried him from our midst. I am, Sir, yours faithfully,

Manchester, Dec. 30th, 1931. HARRY PLATT.

(*Continued from previous page.*)

St. Margaret's Hospital there were 10 babies (plus 5 thers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including ndon, there were no deaths from small-pox, 3 (0) om enteric fever, 39 (8) from measles, 3 (2) from arlet fever, 46 (5) from whooping-cough, 26 (2) from htheria, 43 (11) from diarrhœa and enteritis under o years, and 140 (19) from influenza. The figures parentheses are those for London itself.

Eight of the fatal cases of measles were reported from oke-on-Trent and 11 from Manchester. Whooping-cough counted for 10 deaths in Liverpool, 5 in Birmingham, d 3 in Hull. Five of the deaths from diarrhœa and ritis were notified from Liverpool. Fourteen of those tributed to influenza were in Manchester, 9 in Liverpool, in Birmingham, and 5 each in Bury, Birkenhead, and alford.

he number of stillbirths notified during the week as 197 (corresponding to a rate of 47 per 1000 total irths), including 27 in London.

PROGNOSIS IN LEUKÆMIA.

To the Editor of THE LANCET.

SIR,—So many conflicting statements have been made on the expectation of life in myeloid and lymphatic leukæmia, that I am anxious to obtain more information on this point than my own series of 127 cases affords. This is not usually available from the records of hospitals, many cases having been discharged to the care of their own medical attendant.

I write, therefore, to ask the help of your readers in this matter and to say that I should be very grateful for a brief note on any case that may have come under their observation, mentioning the type of leukæmia, age, and sex of patient, and the duration of life after the diagnosis had been made. I should also like to know whether treatment has included the use of X rays or not.

I am, Sir, yours faithfully,
A. KNYVETT GORDON.

Bedford-square, W.C., Jan. 4th, 1932.

THE ÆTIOLOGY OF "MALTA FEVER."

To the Editor of THE LANCET.

SIR,—With reference to the mention of my name in your journal of Dec. 19th, 1931, the only bacteriological equipment which I received from the then Medical Director-General consisted of air-tight glass chamber incubators in which sterilised agar-agar plates were kept; the sterile gelatine was inoculated with the blood of the patients in Bighi hospital suffering from so-called Malta fever. I made an arrangement with the hospital authorities, that whenever a patient died from that disease I should be sent for, day or night, to get a specimen of the blood and inoculate the sterilised gelatine; the plates were then put into an incubator, where the samples of the micrococcus spread, and were then examined under a high power microscope. As regards receiving apparatus from the Government authorities, the amount was small; it did not include a high power microscope. I personally purchased and paid for an oil immersion Zeiss microscope direct from Jena at a cost of 50 guineas.

If I read a foolish paper at the Epidemiological Society referring to the fever being due to the harbour water, my later work on the subject dealt only with the disease as being due to the micrococci extracted from blood immediately after death, with which the gelatine was inoculated. This refers to a period about 1889. I read a paper on the subject at a meeting of the Epidemiological Society in London, which was published in their journal; I hired 11 high power microscopes and gave a demonstration of the micrococcus cultures grown by me in sterilised agar-agar gelatine. This demonstration was given at the premises of the above society, using Zeiss oil immersion microscopes only.

I am, Sir, yours faithfully,
Lymington, Hants, Jan. 4th, 1932. A. G. P. GIPPS.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. T. C. Patterson is placed on Retd. List with rank of Surg. Capt.

Surg. Comdr. to Surg. Capt.: G. F. Syms and S. Bradbury.

ROYAL ARMY MEDICAL CORPS.

To be Brevet Col.: Lt. Col. W. Benson.

To be Brevet Lt. Cols.: Majs. P. S. Tomlinson and J. M. Weddell.

E. McDonnell, late R.A.M.C., retires on retd. pay.

Col. J. W. West, late R.A.M.C., is placed on half pay.

Maj. T. H. Twigg is secd. for serv. under the Coloni Office.

Lt. H. E. Knott to be Capt.

Lt. F. G. Brown relinquishes his temp. commn.

A. A. Pullar is granted a temp. commn. in the rank of L

ARMY DENTAL CORPS.

Capt. N. H. Medhurst to be Maj.

TERRITORIAL ARMY.

Majs. A. Leggat and E. W. Matthews to be Bt. Lt.-Co

Capts. J. E. Rusby, C. F. Mayne, and O. G. Misquith be Bt. Majs.

Lts. S. G. M. Lynch and J. R. Wright to be Capts.

J. Simpson to be Lt.

INDIAN MEDICAL SERVICE.

Capts. R. W. H. Miller, P. A. C. Davenport, R. T. Adva and W. C. McKee to be Majs.

ROYAL AIR FORCE.

Flight Lts. to be Honorary Squadron Leaders: J. Skeet and A. W. Comber.

Dental Branch: Ernest Sharp is granted a non-perman commission as a Flying Officer.

ROYAL AIR FORCE RESERVE.

Flight Lt. to be Honorary Squadron Leader: T. Walker.

HONORARY SURGEON TO THE KING.

The King has approved the appointment of Air V Marshal John McIntyre, *M.C.*, as an Honorary Surgeon His Majesty, vice *Group-Captain* Henry Cooper, *D.S* who vacates the appointment on retirement from the Ro Air Force.

OBITUARY

NICOL RANKIN, M.C., M.B., Ch.B. Glasg.

WE regret to announce the death of Dr. Ni Rankin at the early age of 47, which occurred Dec. 31st, 1931. He had already established high reputation in London in his special departm of medicine, and his untimely death has cut sh a promising career.

Nicol McNicoll Rankin received his medical edu tion at the University of Glasgow, where he gradua as M.B., Ch.B. in 1908. He was a successful stud and after graduation served both as house physic and house surgeon at the Glasgow Royal Infirma and held resident posts also at the Western Infirma Appointed registrar to the Central London Thr Nose and Ear Hospital, he was serving in this capa at the outbreak of the war, when he joined up regimental duties with the Buffs (East Kent R ment). Here he inspired sentiments of respect affection in so marked a way that the unusual hon was bestowed upon him of election to the Regime Association, membership of which is usually reser for regular army officers. Rankin won the Milit Cross by a conspicuous act of bravery, contin to attend the wounded and dress their injuries un a heavy barrage, after he had himself receive severe wound in the face.

At the close of the war Dr. Nicol Rankin appointed assistant surgeon to the Central Lon Throat and Ear Hospital, and a few years l became full surgeon, and enjoyed at this inst tion just repute as a clinical observer, an opera and a teacher. He had the confidence of his colleag and the students associated with him, while essential qualities were reinforced by a vein Scottish humour which made him a genial compan Much sympathy is felt for his widow and yo family.

BENJAMIN W. THOMAS, M.R.C.S. Eng., L.R.C.P. Lond.

The death took place at his house in Welwyn on Dec 27th, 1931, of Dr. Benjamin Wilfred Thomas, n his seventy-third year.

Dr. Thomas was the son of Dr. Benjamin Thomas f Llanelly, and was educated at Epsom College, whence he proceeded as a medical student to Charing Cross Hospital, where he filled the house appointments. He was for a time surgical registrar and chloroformist to the Royal Orthopædic Hospital, and ook up general practice in 1888 in Welwyn, where he continued to practise for 40 years, retiring owing to ill health in 1928. His work was continued with assiduity until this date, in spite of the fact that in 1916 and again in 1917 he underwent operations for cataract. Of this remarkable triumph over a serious physical disability he was rightly proud.

MEDICAL NEWS

University of London.

At recent examinations the following candidates were successful —

M.S.

Branch I. (Surgery)—* P. B. Ascroft, Middlesex Hosp.; A L Light, Univ. of Leeds, D. W. C. Northfield, Guy's Hosp, K H. Watkins, Univ. of Manchester, and Philip Wiles, Middlesex Hosp.

* University medal.

Branch IV. (Laryngology, Otology, and Rhinology)—C. A. Amesur, St. Thomas's Hosp, and T D. Deighton, St. Bart's Hosp

Forthcoming Lectures.—Eight lectures on the Use of X Rays in Physiological Investigations will be given in the Physiological Theatre at Guy's Hospital, S.E., at 5 P.M. on Jan. 18th and 25th (Prof. J. M. Woodburn Morison); Feb 1st and 8th (Prof. H. A. Harris); Feb. 15th and 22nd (Dr. A. E. Barclay); and Feb 29th and March 7th (Dr. A. F. Hurst)—Three lectures on Serological Studies of Vaccinia will be given by Dr. W. J. Tulloch, professor of bacteriology in the University of St. Andrews, at St. Thomas's Hospital at 5 30 P.M. on Jan. 18th, 19th, and 20th.—The course on Genetic Principles in Medicine and Social Science will be continued during the Lent term by Prof. Lancelot Hogben at the London School of Economics at 5 P.M. on Fridays from Jan. 15th.—Mr. H. R. Ing, D Phil., will give six lectures on Chemotherapy at University College at 5 P.M. on Tuesdays from Jan. 19th.—Dr. S. J. Cowell, professor of dietetics in the University, will give four lectures on Modern Aspects of Nutrition at Bedford College at 5.15 P.M. on Wednesdays from Feb. 3rd to 24th.—Three lectures on the Feeding and Nutritional Disease of the Infant will be delivered by Prof Leonard Findlay at St. Bartholomew's Hospital Medical College at 5 30 P.M. on Feb 8th, 9th, and 12th.—Dr A. J. Clark, professor of materia medica in the University of Edinburgh, will lecture on the Reaction between Drugs and Cells at University College at 5 15 P.M. on Feb 26th and 29th and March 1st.

A list of advanced lectures and practical courses in physiology to be given during the present session may be had from the Academic Registrar.

Society of Apothecaries of London.

At recent examinations the following candidates were successful.—

Surgery—G. A Dickson, Univ of Sheffield; W. Hertzog, Guy's Hosp, W. B Mattar, St Mary's Hosp.; C Morgan, Charing Cross Hosp; and B Rivlin, Middlesex Hosp.

Medicine—F. Crowther, Guy's Hosp; H. T. Giblin, St. Mary's Hosp., R. F. Hawke, London Hosp, W. W. Parry, Guy's Hosp, S Ramarao London Hosp., B Shapiro, Universities of Moscow and Witwatersrand, E Teplitzky, Univ. of Berne and St. Mary's Hosp, E O Watson, St. Bart.'s Hosp.; and H A. T. Wells, Guy's Hosp

Forensic Medicine—J. H. Beale, Universities of Oxford and Sheffield, F Crowther, Guy's Hosp; H. T. Giblin, St Mary's Hosp; J Irger, Univ. Coll. Hosp., V. R. O. Lahanmi, Univ. of Manchester, R. Perkins, St Bart's Hosp, and H A T. Wells, Guy's Hosp.

Midwifery—G A Dickson, Univ. of Sheffield, R N. Gillespie Royal Free Hosp, R F Hawke, London Hosp, A A Kahn, Med Coll, Calcutta, E J. Littledale, Guy's Hosp, A J McBrearty, Queen's Univ, Belfast, and J. T Moohala Israckel Queen's Univ, Belfast

The following candidates, having completed the final examination, are granted the diploma of the Society, entitling them to practise medicine, surgery, and midwifery.—H T. Giblin S Ramarao R N Gillespie, E O. Watson, C Morgan, and H A T Wells

Royal College of Surgeons of England.

This month Sir Arthur Keith will give six Hunterian lectures entitled Malformations of the Human Body considered from a New Point of View. They will be delivered in the theatre of the College, at 5 P.M., on Mondays, Wednesdays, and Fridays, from Jan 18th to 29th, inclusive, and will be illustrated by specimens from the museum.

Board of Control.

On the retirement of Mr. O. E. Dickinson, the Board of Control have appointed Mr. P. Barter to be their secretary, and Mr. W. Fairley to be assistant secretary.

Medical Society of Individual Psychology.

The annual dinner of this society will be held at The Florence Restaurant, Rupert-street, London, W., on Thursday, Jan. 14th, at 7.15 for 7.30 P.M.

West London Medico-Chirurgical Society.

At a meeting of this society, to be held at the West London Hospital to day, Friday, Jan. 8th, at 8 30 P.M., Mr. Malcolm Donaldson and Prof. A. Piney will open a discussion on the Treatment of Carcinoma.

The "Chinese Medical Journal."

The *National Medical Journal of China* has now combined with the *China Medical Journal*, and from now onwards will be issued monthly under the new title of the *Chinese Medical Journal*. It will be the only medical journal published in China in the English language. Its address is: National Medical Association Building, Tzepang and Avenue-roads, Shanghai.

Winter in England.

As announced in our last issue, a meeting of those interested in the development of British coastal health and holiday resorts will be held at the Institute of Hygiene, 28, Portland-place, London, W.1, at 3.30 P.M. on Monday next. Lord Riddell will take the chair, and the objects and methods of a proposed British Seacoast Association will be described by medical and other speakers. The hon. secretary, Miss Herz, may be addressed at the institute.

Congress of Sanitary Science.

The third Congrès International de Technique Sanitaire et d'Hygiène Urbaine will be held at Lyons from March 6th to 9th The principal subjects of discussion will be the hygiene of transport, habitations, and places of assembly; hospitals; social work; atmospheric pollution; disinfection; and industrial hygiene. Further information may be had from Dr. Garin at the offices of the Congress, Rue Menestrier, Lyon, France.

Order of St. John of Jerusalem.

The King has sanctioned the following promotions in and appointments to the Venerable Order of the Hospital of St. John of Jerusalem:—As Officers: Maj-Genl. W. V. Coppinger, Lt. Col. J. S Purdy, Maj. A. B. Cardew, Col. A. M. Connell, Dr. G. J Linklater, and Dr. R. Owen. As Associate Officer: Lt. Col. H. Suhrawardy. As Serving Brothers Dr. R. V. Clayton, Dr. F. S Hardy, Dr F. W. M. Palmer, Dr. L L. Westrope, Dr. W. Mailer, Mr. O. A. Ehrmann, and Dr. E S B. Hamilton.

Appointments

BROWNE F W, M B Oxon, has been appointed Medical Officer to the Post Office, Bristol

Vacancies

For further information refer to the advertisement columns.

Barnsley, Beckett Hospital and Dispensary—Cas O £250
Beckenham, Kent, Bethlem Hospital, Monks Orchard—Res H P. At rate of £150
Birmingham, Little Bromwich Hospital for Infectious Diseases—Jun Asst. M O. £300
Birmingham Maternity Hospital—Res M O £200
Bolingbroke Hospital, Wandsworth Common, S W.—H.P. At rate of £120.
Bradford Royal Infirmary—Res Surg O. £225
Brighton, Royal Sussex County Hospital—H S £150.
Cambridge, Papworth Village Settlement—Third Asst. M O. £200.
Cardiff, Welsh National School of Medicine—Demonstrator in Pathology and Bacteriology. £250
Carlisle, Cumberland and Westmorland Mental Hospital—Jun. Asst M O £350.

Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—Sen. and Jun. H.S.'s. At rate of £120 and £100 respectively.
[illegible] *Derbyshire Royal Hospital.*—H.S. £150. [illegible] 50.
[illegible] tologist.
[illegible] —H.S. At rate of £150.
Evelina Hospital for Children, Southwark, S.E.—H.P. At rate of £120.
Glasgow Corporation.—P.H. Dept. Pathologist. £800.
Guildford, Royal Surrey County Hospital.—H.S. £150.
Hampstead General and N.W. London Hospital, Haverstock-hill, N.W.—H.P. At rate of £100.
Hertford County Hospital.—H.P. At rate of £150.
Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. and H.S. Each at rate of £50.
Hove Hospital, Sackville-road.—Res. M.O. £200.
Huddersfield Royal Infirmary.—Res. Surg. O. At rate of £225. Also H.S. At rate of £150.
India, British Empire Leprosy]Relief Association.—Medical Man. Rs.1000 to Rs. 1200 per mensem.
Kingston-upon-Hull, Anlaby-road Institution.—Asst. M.O. £300.
Liverpool and Samaritan Hospital for Women.—Hon. Asst. Surgeon.
Liverpool, David Lewis Northern Hospital.—Four H.S.'s and Two H.P.'s. Each at rate of £100.
Liverpool, Royal Children's Hospital.—Second Res. M.O. for Heswall Branch. At rate of £120.
L.C.C.—Asst. M.O.'s for Panel School Medical Work. 30*s.* per session.
Manchester, St. Mary's Hospitals.—Four H.S.'s and Jun. Asst. M.O. All at rate of £50.
Margate, Princess Mary's Hospital for Children.—Res. Med. Supt. £950.
Mile End Hospital, Bancroft-road, Mile End, E.—Asst. M.O. £350.
National Hospital, Queen-square, W.C.—Hon. Surg. Asst.
Newcastle General Hospital, Newcastle-upon-Tyne.—Res. Med. Assts. Each at rate of £150.
Northampton General Hospital.—Hon. Ophth. Surgeon.
North Middlesex County Hospital, N.—Res. Asst. M.O. £400.
Norwich, Norfolk and Norwich Hospital.—H.S. Also Cas. O. and H.S. Each £120.
Queen's Hospital for Children, Hackney-road, E.—Surg. to Ear, Nose, and Throat Dept.
Retford, Notts, Rampton State Institution for Mental Defectives.—Med. Supt. £1000. Also Fourth M.O. £400.
St. Alfege's Hospital, Vanbrugh Hill, Greenwich, S.E.—Asst. M.O. £350.
St. John's Hospital, Lewisham, S.E.—Res. H.P. and H.S. Each at rate of £100.
St. John's Hospital, St. John's Hill, S.W.—Asst. M.O. £350.
St. Mary Abbot's Hospital, Marloes-road, Kensington.—Asst. M.O. At rate of £250.
St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—Anæsthetist. £25.
Sheffield, Children's Hospital.—H.P. and H.S., and Cas. O. At rate of £100 and £80 respectively.
Sheffield Royal Infirmary.—Ophth. H.S. At rate of £80.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Hon. Surg. Reg. Also H.P. and H.S. Each at rate of £100. Also Out-patient Anæsthetist. 10*s.* 6*d.* per attendance.
Warrington Infirmary and Dispensary.—Sen. and Jun. H.S.'s. £225 and £175 respectively.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at New Southgate (Middlesex) and Falmouth (Cornwall).

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, Jan. 12th.—5 P.M., THERAPEUTICS AND PHARMACOLOGY. 4.30 [illegible] Oxygen Apparatus. Paper: Prof. [illegible] Uses of Oxygen in Medicine. [illegible] G. Douglas and Dr. R. Hilton. 8.30 P.M., PSYCHIATRY. Cinematograph Demonstration. Dr. Noel H. M. Burke: Some Aspects of Mental Deficiency.

Wednesday.—5 P.M., SURGERY: SUB-SECTION OF PROCTOLOGY. Cases: Mr. W. S. Perrin: 1. Chordoma. Mr. L. E. C. Norbury: 2. Extensive Prolapse of Rectum. Specimens: Mr. Ernest Miles: 1. Recurrent Procidentia Recti with Diverticulosis. 2. Secondary Sarcoma of Pelvic Colon. Mr. L. E. C. Norbury: 3. Endothelioma of Rectum. Mr. W. B. Gabriel: 4 and 5. Carcinoma of Cæcum. Mr. Lawrence Abel: 6. Myxo-fibroma of Small Intestine. 7 and 8. Lipoma of Large Intestine. 9. Fibroma of Anterior Surface of Cæcum. Mr. Naunton Morgan: 10. Carcinoma Simplex of Rectum. 11. [illegible] Rectum. Other cases and specimens [illegible] per: Mr. Lawrence Abel: The [illegible] by coloured cinematograph film).

Friday.—5.30 P.M., PHYSICAL MEDICINE. Paper: Mr. G. C. Simpson, D.Sc. (Director of Meteorological Office): Meteorological Factors which may Affect Health. 8.15 P.M., OBSTETRICS AND GYNÆCOLOGY. Specimens: Mr. T. G. Stevens: 1. Rhabdosarcoma of the Cervix. Mr. L. Carnac Rivett: 2. Foreign Body Found in the Intestine after Cæsarean Section Ten Years Previously. Paper: Prof. E. C. Dodds: The Bearing of Recent Research on the Sex Hormones on Clinical Obstetrics and Gynæcology. Discussion: Speakers: Prof. A. S. Parkes, Dr. H. Gardiner-Hill, and Dr. B. P. Wiesner. 8.30 P.M., RADIOLOGY. Discussion: Some Physical and Medical Aspects of X Ray D[illegible] Mr. W. V. [illegible] Radiation [illegible] Old and N[illegible] in Cancer. [illegible] Disease. Followed by Dr. A. Burrows, Dr. Goldsborough, Prof. Hopwood, Dr. J. E. Lynham, Dr. G. Scott, Dr. J. Webster, and others.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.1.

Monday, Jan. 11th.—8 P.M., Pathological Meeting.

HARVEIAN SOCIETY OF LONDON.

Thursday, Jan. 14th.—8.30 P.M. (at the Paddington Town Hall, W.). Annual general meeting. Presidential address by *Sir Thomas Horder.*

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Friday, Jan. 15th.—5 P.M. (at 1, Upper Montague-street, [illegible]) Discussion on Causes of the [illegible] Mortality, opened by Dr. [illegible] Ernest Ward.

SOCIETY FOR THE STUDY OF INEBRIETY.

Tuesday, Jan. 12th.—4 P.M. (at 11, Chandos-street, W.). Discussion on Mental Defectiveness and Alcohol and Drug Addiction. Opener: Dr. W. Norwood East.

BRITISH INSTITUTE OF RADIOLOGY, 32, Welbeck-street, W.

Thursday, Jan. 14th.—8.30 P.M., Further discussion of Dr. Ffrangcon Roberts's paper on the International Protection Recommendations.

Friday.—Morning visit to the Research Department, Woolwich.—5 P.M., Discussion on Bone Tumours. (Opener: Dr. James Brailsford.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, Jan. 11th, to [illegible].—MEDICAL SOCIETY OF LONDON [illegible] W., Monday, 8.30 P.M., Dr. W. L[illegible] Endocrines and the Sympathetic Nervous System. (First of six lectures on Endocrinology. Fee.) Wed., 4 P.M., Dr. E. H. R. Harries: Modern Treatment of Common Infectious Diseases. (First of nine lectures on Treatment. Fee.) Syllabuses from the Fellowship.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, Jan. 11th.—10 A.M., Gynæcological Wards [illegible] Genito-urinary Op[illegible] 11 A.M., [illegible] Medical Surgical Wards. [illegible] Surgical, Eye, an[illegible]

Tuesday.—9.30 A.M., [illegible] Ward Demonstration; [illegible] A.M., Throat Operations. 11.30 A.M., Surgical Demonstration. 2 P.M., Operations; Medical, Surgical, and Throat Out-patients.

Wednesday.—10 A.M., Medical Wards; Children's Medical Out-patients. 2 P.M., Medical, Surgical, and Eye Out-patients. 2.30 P.M., Gynæcological Operations. 4.45 P.M., Venereal Diseases Demonstration.

Thursday.—10 A.M., Neurological Department. 11.30 A.M., Fracture Demonstration. 2 P.M., Medical, Surgical, Eye, and Genito-urinary Out-patients. 2.30 P.M., Operations.

Friday.—10 A.M., Medical Wards, Skin Department, Dental Department. 12 noon, Medical Lecture. 2 P.M., Operations, Medical, Surgical, and Throat Out-patients.

Saturday.—9 A.M., Throat Operations. 10 A.M., Medical Wards, Surgical and Children's Out-patients.

ST. MARK'S HOSPITAL, City-road, E.C.

Thursday, Jan. 14th.—4.30 P.M., Dr. J. Browning Alexander: Constipation and Obstipation.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark-hill, S.E.

Thursday, Jan. 14th.—9 P.M., Dr. H. A. Lucas: Serum Treatment in Practice.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

Friday, Jan. 15th.—4 P.M., Mr. J. D. McLaggan: Eczematous Condition of the Ear and Nose.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

Tuesday, Jan. 12th.—5 P.M., Sir E. Graham Little: Cicatricial Alopecia.

Thursday.—5 P.M., Dr. W. J. O'Donovan: Stocking Erythroderma.

WESTERN INFIRMARY, Glasgow.

Wednesday, Jan. 13th.—4.15 P.M., Dr. George A. Allan: Medical Cases.

NOTES, COMMENTS, AND ABSTRACTS

PREVENTIVE MEDICINE IN ITS RELATION TO AVIATION.

By E. Goodwin Rawlinson, M.D., D.P.H.,
DIRECTOR OF THE BACTERIOLOGICAL DEPARTMENT, ROYAL INSTITUTE OF PUBLIC HEALTH.

Air transport has now become so important a factor in the life of the community that preventive medicine must seriously take into account the new problems that inevitably have arisen.

The Pilot.

Medicine in aviation has naturally, up to the present, been chiefly concerned with the pilot. He is the keyman of all flying. His selection and fitness must always be the primary consideration, and examinations at fixed intervals by the same highly trained specialists are necessary to ensure that his efficiency is unimpaired; to note the influences and conditions under which he works. Everything that has a bearing, directly or indirectly, upon his flying health should be observed and rigidly supervised.

Many ingenious tests have been devised for this purpose, and in no other branch of medicine has the psychological side been so well stressed, and its importance so well appreciated as in the selection and care of the aviator.

The medical branch of the Royal Air Force has shown great resource and initiative in dealing with the various difficult problems with which it has been so violently faced, and the pioneer work of Flack, Stamm, Head, and many others,[1] necessarily sets a standard for medicine dealing with the pilot in civil aviation. Most of the pilots engaged in civil aviation transport have been trained in the Service and the system of short-term engagement makes it likely that this will be so for a considerable time to come.

The candidate to become a pilot in civil transport is finally examined at the Air Ministry in London. The medical examinations are carried out here by the same people, the same apparatus, under the same conditions, in the same atmosphere. It will be readily understood that, for such vital, stringent, and complex tests and such comparatively new work, the advantage of these being carried out always by the same personnel is great, and that it will be very difficult to delegate them to a decentralised authority. The value of impressions obtained, too difficult to define, the intuitive knowledge that must be gained, all tend to make this extremely personal and limiting. So too with such work still in its infancy, new devices and experiments are continually being elaborated, which could only be properly evaluated by those already steeped in the work.

The would-be pilot undergoes a super-insurance examination as to his family history, his personal habits, tastes, hobbies; his education and the minutiæ of his occupation since his school days. This being satisfactory, his selection will depend upon what are known as physical efficiency tests.[2] These are devised to determine the conditions of his cardiovascular system, respiratory capacities, vision, hearing, nervous and muscular reactions. To pass these tests he must prove to be a piece of perfect mechanism both mental and physical, with capabilities of unerring judgment. After a period of training, if satisfactory, he receives certificate B. (the public transport certificate). This must be renewed at six-monthly intervals after re-examination. A woman pilot holding such certificate is re-examined every three months.

The conditions of the pilot's work obviously are of the utmost importance and should come under the supervision and control of a competent authority—at present the Air Ministry. They have a vital effect on his efficiency, and the peculiar nature of his work is such that the easement of any arduous factor makes for safer flying.

The length of flying-time must be regulated, the periods of waiting must be considered; where must the pilot be housed during such periods of his employment, what must he do that he be not depressed—a condition fraught with trouble for pilots? His reaction to night flying should be noted.

The employing company cannot always appreciate that small and apparently trivial difficulties are vital in their reactions. The maker of the machines, in his engineering enthusiasm, unconsciously adds to the pilot's troubles by altering or adding controls, changing what has been an automatic reaction to an extraconscious action—a possible source of error in rapid judgment. The necessity for standard controls cannot be too strongly urged; and every effort should be made to lessen the number of instruments the pilot must watch—air speed indicator, altimeter, oil and petrol gauges, compass, &c.—and these tend to increase. So, too, everything that will minimise the result of an accident to him, such as the special padding of the cockpit, the automatic parachute, tends to give him a certain relaxation of the tenseness of expectancy.

These are all subjects that come under the purview of preventive medicine in aviation as well as a consideration of the length of a pilot's occupational life, the problem of his after career, and the assurance of more than a pittance when his comparatively short flying life is done. It must affect his efficiency if he has a conscious or a subconscious worry as to what is to become of his wife and family, in case of total disability, or—feeling a lessened vitality from a quickening staleness—as to the results of his next medical examination.

It must always be an axiom that the pilot (apart from the machine) is the paramount factor of flying.

The Passenger.

Air transport companies between Great Britain and the continent carried 48.253 passengers in 1929.[3]

AIR-SICKNESS.

There are no statistics available to show how many of the 48,253 suffered air-sickness, but it is stated to be not negligible. Apart from the mental bias to sickness and the unusual movement, probably four main factors tend to operate in the causation of this troublesome condition: poor ventilation, lack of warmth, noise, and vibration: the first being the most important. A reasonable altitude, per se, does not appear to have any bearing on sickness.

The problem of changing the air of the small cubic space allowed to each passenger is a difficult one. To change the air sufficiently often to keep it fresh means draughts. If draughts are prevented then the sense of "stuffiness" arises, due, as Leonard Hill[4] has shown, to lack of the removal of the air next the skin and enmeshed in the clothing.

The heating of the air presents some engineering difficulties. Air heated by contact with hot pipes leading from the exhaust may contain noxious gases and the possibilities of leakage. Humidity and warmth might be measured and controlled by passing air through steam.

The Handley Page 42-seater on the India route has a cubic capacity of approximately 4000 c. ft., giving slightly less than 100 c. ft. per passenger. Hot and cold air inlets are provided at each pair of seats. The *Argosy* on the Paris service, seating 20 passengers, gives about 54 c. ft. to each person. (This does not compare unfavourably with crowded suburban trains.) A room in a dwelling-house is required to have 1000 c. ft. space for each person.

We know from experience that continuous and particularly unusual noise is fatiguing; it is one of the problems of our mechanised age. The noise of the actual explosion of the cylinders of the engine may be reduced, but in so doing, Heald [5] has pointed out, the unpleasant screaming of the timing gears then become predominant. Vibration he also notes can become fatiguing, and thus may be a reflex cause of sickness. Exhaustive experiments in the sound proofing of aeroplane cabins are being carried out by different authorities.[6]

An investigation promoted by the Daniel Guggenheim Fund for the Promotion of Aeronautics [7] was concluded by the observation that few people are troubled by air-sickness in properly built and efficiently piloted aircraft.

Research carried out by Marrack,[8] as to a fundamental cause of sea-sickness, showed that ketosis occurred in nearly all subjects within 24 hours after vomiting commenced, but that it was incidental, and evidence of a metabolic change which itself may be the cause. According to Flack [9] the connexion between sea- and air-sickness appeared to be slight, though in cases where the labyrinth was unduly sensitive the subject would be both sea-sick and air-sick. Flack also noted that where the labyrinth did not seem to be involved, ocular muscle imbalance was the primary condition. Maitland,[10] in work carried out at the same time as both the above, observed that a passenger can only partially counteract a sudden, unexpected arrest of movement and a change of direction, by bodily adjustment; "the eye fails to pick up the datum levels, to rectify erratic information received by the semi-circular canals."

Much general experience goes to show that all subjects react very differently, as to the various factors which set up the impulse, and that different senses and functions are involved in different people.

DISPOSAL OF EXCRETA.

The Air Ministry regulations [11] at the present time prohibit the dropping of articles from the air, with certain exceptions, but the exceptions apply to excretal matter, a problem that requires urgent attention. It is almost safe to say that at the present time, when a passenger or a pilot urinates or defæcates whilst in the air, the excreta, liquid and solid, is simply allowed to scatter on the four winds of Heaven. This anachronism would never have been permitted had there been visible evidence. No palpable mass can be observed—the height at which it is released being sufficient to cause division into small particles or drops.

The layman will perhaps argue that such division and the exposure of the fine particles to wind, rain, and sun (particularly the sun) is all that can be desired to make such material harmless, although he probably would object on æsthetic grounds; and it may be argued by the more knowledgeable that the bacterial content of the healthy intestine is not of a disease-producing type and that those who are flying or travelling by air are the most likely to be of a healthy normal type. It has been estimated, however, that about 1 in 1000 of the population is a typhoid carrier [12]—apar tfrom other intestinal disease carriers—and there appears no reason why human carriers of the salmonella group of bacteria should not exist. The dysentery carrier cannot be absolutely disregarded, and on the air routes of Africa, Asia, and South America, dysentery, cholera, and helminth carriers are important, and can be contributors to disease broadcast in such a manner.

If the above estimate is right the Imperial Airways and other companies possibly transported 27 typhoid carriers in 1929. True, they may not all have defæcated or urinated whilst in the air, but it is certain that a proportion of them did so.

What happens to the finely divided particles? Each minute mass is attached to a droplet of moisture and the bacteria present are protected with a coating of fæcal matter from being killed by the sun's rays and the moisture present is necessary for their existence. In calm weather a gradual deposition takes place in the area in which it is dropped. In windy weather it is carried great distances: it may remain suspended in the air, wafted by slight currents; but whatever the weather or conditions there is every possibility of its being finally deposited or blown direct into an open water-supply, on to human food, or taken into the lung. Air routes pass over reservoirs and water-supplies, or in close proximity. Close or distant, the danger exists.

It may be said that we are accustomed to breathing in an atmosphere laden with bacteria among which are intestinal organisms, or that the possibilities of disease arising from aeroplane passenger traffic at present is very slight. But each year sees a larger number of people taking to air, each year the ends o the earth are brought closer, and where definit air routes are established in countries where intestina disease, such as dysentery and cholera, are bot endemic and epidemic, the increase in the dange becomes more marked.

Suggested measures.—There appear to be severa possible ways for dealing with excreta on aeroplane but the present design and construction of th machine is not such as to expect or allow elaborat weighty, or bulky mechanism for such purpose and sanitary authorities would be well advise to be satisfied with simple and possibly primiti devices at first.

For passenger-carrying machines a small, standar aluminium tank or box could be fitted in the lavato containing a small amount of disinfectant of high coefficie The tank should be of sufficient size to take the excre of half the number of passengers carried. The size necessa for ten people for a three to four hour journey would approximately 1½ gallons. (The amount of excreta 24 hours per person is taken as about 50 oz. of urine and average of 5 oz. of fæces.) The tank would be prefera of an ink-well pattern; a detachable funnel-top fitting i a cylindrical container with an incurved rim. Th would be replaced at the air-port by one of a stand pattern, and the used one emptied, disinfected, and prepa ready for use again.

A further development might be devised at a later dat a tank jacketted for steam, if such were available, or hot from the exhaust, by which the excreta would be rapi dried. This would necessitate an exhaust ventilat for fumes and perhaps a method of removing the dr material from the chamber, but if the heat generated sufficient to dry the material very rapidly, the tank wo have the advantage of a very small size and diminis weight of excreta.

A device for breaking down the solids by compressed and then rendering them innocuous before discharge into air would probably require too complex machinery practical use.

For a single-seater machine, a valved funnel arrangem could be planned with a plenum device for forcing the ma by air to a small tank at the rear of the fuselage.

Excreta taken from the machines at air-ports wo readily be dealt with where the air-port was favoura situated near a large town, but the establishm of air-ports in primitive surroundings would ne sitate the method of disposal best suited for the a

THE CARRYING OF DISEASE.

As civil aviation increases and internati boundaries become of lesser import, the utm stringency will be imperative to prevent epidem The Royal Air Force as a fighting force has con of all the units it carries, but in civil aviation probl arise with regard to the transport of units over w much less control can be exercised; unless, as poin out by Massey,[13] the very purpose of the speed aviation is destroyed.

It is now possible to travel half round the w whilst sickening for a disease. A man could d a typhoid-infected water in the Antipodes show no signs of it until after he had disembar from an aeroplane at Croydon. And though danger of the introduction of disease into this cour by aeroplane is not yet very great, each day bring a little closer to the subtropics and the tropics.

The danger of the spread of the yellow f mosquito across Africa by air travel has already b urged by James.[14] Draft regulations concerning pe of menace already exist and in some countries, ch as South America, are actually in force; coast-ise seaplane services along yellow fever regions ust land and embark passengers at a certain distance om shore.

As an Empire country we must necessarily envisage l the possibilities of the spread of tropical disease r air: cholera, dysentery, and plague, not only into is country, but from one Dominion to another. et is seems that our greatest immediate danger om this means is the introduction into, and the read in the British Isles, of influenza, the exanthe-ata and the diseases caused by filtrable viruses. n 1930 42,435 passengers were carried between the ontinent and Great Britain by air.[15] With the cursory upervision possible at present, how great a potentiality r these diseases in their incubation periods?

Without nullifying the very object of aviation, he control of communicable disease will prove to be ne of the most difficult problems preventive medicine as had to face. At present our quarantine is under he primary control of H.M. Customs and aeroplanes re cleared as ships. Unless blatantly ill no sick assenger would have much difficulty in evasion, nd virulent disease could land with little hindrance.

A bill of health from the port of embarkation has een suggested. This is already in force in certain ountries: often it may have little value. It will be eadily seen that a passenger hurried by car to the air-port with just enough time to embark (and this is not unusual) is somewhat perfunctorily examined. Also, different countries have not the same standards.

The possibilities of the future would seem to lie in the following directions:—

(1) Reorganisation of the quarantine service and its transfer, as far as aviation is concerned, to the Ministry of Health. At present aircraft in this respect are governed by maritime regulations. Conditions are so different it is self-evident that reorientation is inevitable.

(2) The employment of whole-time medical officers in such quarantine service, and the establishment of small quarantine hospitals at air-ports.

(3) An extension of the use of consular reports telegraphed as to the daily health at this official's station as well as the reports of the Office Internationale d'Hygiène Publique.

(4) The establishment of regulations of an elastic nature and subject to frequent revision.

(5) Immunisation preliminary to travel from epidemic areas.

Some of these points have been discussed by Holden.[16]

The knowledge that a close scrutiny of passengers was carried out on disembarkation would tend to deter a certain number of incubationary carriers. It may be possible at some future date to devise some rapid method of diagnosing "not quite wellness," because it is this state, or lack, of health that must almost always be considered in the aeroplane passenger.

It must be emphasised that authority should endeavour to carry out a measure of control, efficient and elastic, in order that the purpose and development of aviation be not hampered. Even under the best auspices there is no doubt that the more the extension of our freedom as to time and space, the more the restriction of our liberty, where the health of the community is involved. (The dangers of transmission of disease by aircraft apply to all forms of transport, and it would be reasonable, whilst setting this house n order, to give some attention to our far from rfect protection from the same type of disease on oss-channel boat traffic and in trains.)

Accidents.

Confidence in aircraft is becoming established. The number of accidents involving regular passenger traffic may be regarded as almost minimal. During the year 1929–1930, with the Imperial Airways one accident occurred and four persons were killed representing one killed per 360,000 miles flown or one killed for 6270 passengers carried.

On examining the causes of accidents, French figures[17] for 1923–1925 are available and the impressive fact emerges that out of 100 accidents the percentage of causes are in almost constant proportion—over half are due to faulty airmanship (errors of judgment) and less than one-quarter to engine failure. American statistics[18] bear this out. They show about 56 per cent. due, as they put it, to personnel, and 19 per cent. to power plant failure. Our own figures for 1929[19] are still higher, 70 per cent. due to errors of judgment (faulty pilotage). These figures emphasise very strongly the urgent necessity of considering no factor too trivial where the pilot is concerned.

All first-aid outfits on passenger machines should include large and small dressings, iodine or other antiseptic in ampoules, spirits of ammonia, and a dressing for burns. All air-ports should be equipped with a dressing station complete with emergency tools and fire extinguishers.

Surgery in connexion with aviation differs but little from that concerned with accidents generally: mainly in degree. Major injuries do not bulk so largely as might be expected. An admirable and interesting analysis of such accidents is given in a work by Graeme Anderson.[20]

Merchandise.

The carrying of merchandise in ships from foreign ports calls for the inspection of cargo for disease-carrying vermin such as rats which may be infested with plague, fleas, or actual carriers of this and other diseases. Cargo and ship must be disinfected: deratisation and measures for rat-proofing carried out.

The same applies, on a small scale at the present time, to merchandise carried in aeroplanes. Such traffic is still in an elementary stage: mail, gold, and precious stones are common air cargoes but with an extension of such traffic to include materials or foodstuffs, a search for parasites, rats, and insect pests will be imperative.

A new condition also arises to that obtaining in ship transport. The shortened period of the journey by aeroplane may allow arthropod disease-carriers to be landed alive in this country that would not otherwise have survived the longer period on a ship. Other insect pests, so introduced, might well have an economic importance in causing destruction of plant or cereal crops.

The entomologist has made use of the aeroplane in the search for and distribution of the natural enemies of similar pests; locusts and grasshoppers are sprayed from the air, in the effort to arrest their destructive progress. The sanitarian has been able to destroy mosquito larvæ over large tracts of country by spraying larvicides from planes.

Health Services.

The aeroplane has already proved of great value in countries where natural cataclysms frequently occur and where ordinary means of communication are destroyed. Rapid organisation of sanitary measures is an urgent necessity after earthquakes or great floods for first-aid work, to prevent epidemic disease, establish food- and water-supplies, and to rush chlorinating apparatus and disinfectants to the affected areas. The recent earthquake in New Zealand and the large flooded districts of the Mississippi are apt examples.

Mobile laboratories, portable X rays and operating units are not dreams of the future in aviation, but are either in being or on the way to reality. The ambulance aeroplane is a standard Royal Air Force equipment. Antitoxin has been hurried to Alaska; cultures of cholera vibrio have been brought from Basra by air to London for the preparation of vaccines to be returned in the same manner, to replenish depleted supplies during an epidemic.

The health services of the future also promise a use of aviation for therapeutics, metabolism is stimulated by flying—its tonic effect is marked: airmen have also noticed that the common cold reacts favourably to flights at high altitudes. But in a country like England where sunlight is so often infrequent one can foresee the possible establishment of sunlight clinics in the air—airships for altitude treatment of heart and respiratory diseases. Instead of prescribing a child a few minutes exposure to the sunlight lamp, we may be ordering a flight at such and such an altitude for half an hour. We have a Leysin directly over our heads all day and every day.

Finally, medicine is to gain from the meteorological research now being carried out on the strata of air at very high altitudes.

HOCKEY INJURIES.

THE casualties at football in America, described by our correspondent from U.S.A. on p. 100, are more fatal and more serious than one would expect, even in the course of a violent game. That few disabling accidents follow hockey has recently been shown by Dr. A. Arnold,[1] of the medical department of the Leipzig University Institute for Physical Exercises. He has recently published his observations on injuries received at hockey in a paper based on their occurrence in 2152 games in which over 23,000 players took part. Like Dr. Glass,[2] who had made similar observations on sets of hockey players, Dr. Arnold classified the injuries into two groups according as the person affected was obliged to give up playing for from three to five minutes, or to abandon the game altogether. In men's teams the incidence of injuries was 0·35 per cent., in boys' teams 0·25 per cent., and in women's and girls' teams 0·34 per cent., or a total incidence of 0·33 per cent. In 38 per cent. the injury was caused by the hockey stick, and in 19 per cent. by the ball, while 43 per cent. were classified as due to indirect causes—i.e., not peculiar to hockey, but such as might occur in any sport—e.g., a fall or collision with another player. The frequency of injuries varied with the different groups of players. As regards the site of the injuries inflicted by the hockey stick the head was affected in 43 per cent., the lower extremities in 33 per cent., the upper extremities in 17 per cent., and the trunk in 7 per cent. of the accidents. The sites of the injuries inflicted by the balls showed a somewhat similar distribution. On the other hand, in injuries due to indirect causes the upper and lower extremities were most frequently affected. The duration of the incapacity caused by the injury was in most cases very short. Only three of the 30 players injured by the stick and only three of the 15 injured by the ball were unfit for playing for longer than a month. On the other hand, of 34 injured by indirect causes, 20 were still unable to resume playing after a month. Three had to give up hockey altogether—one from injury to the kidney and two from injury to the knee. Dr. Arnold comes to the conclusion that since serious injury seems to be rare, and the muscular movements which hockey calls into play are of great variety, the game should be recommended from the medical point of view.

COMPULSORY PASTEURISATION OF MILK.

THE Manchester public health committee has approved a memorandum from Dr. R. Veitch Clark, the medical officer of health, proposing that the city council should take powers to insist that all the milk supplied to the city—except certified and Grade A (tuberculin tested)—should in future be pasteurised. As a condition of registration in the business it is intended that the authorities should require the installation of a satisfactory pasteurising and cooling plant, and should undertake the necessary examination and inspection. In order to obviate hardship it is suggested that a year should elapse between the passage of the act and its enforcement. The *Manchester Guardian* states that already about three-quarters of the city's milk-supply is pasteurised.

THE JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH.

THE annual report of this institution shows that the work initiated there is being steadily carried on. During the year 97 new cases and 1150 additional notes were added to the files, while 795 specimens were examined in the laboratories. A complete survey of the records having now been made, certain groups of cases are to be investigated in furtherance of the principles of Sir James Mackenzie's viscero-motor and viscero-sensory reflex theory. Individual members of the staff have studied the ætiology of the common cold and its relationship to carbohydrate intake, the effect of fatique on the position of viscera, the cause of bacilluria, and have surveyed the physica state of children under 5. The scheme of continuou observation of children up to school age is a usefu means of investigating the primary causes of ill health and of ensuring early treatment.

Births, Marriages, and Deaths

BIRTHS.

ANDERSON.—On Dec. 27th, 1931, at Hong-Kong, the wife James W. Anderson, M.B., Ch.B., F.R.C.S. Ed., of daughter.

CHITNIS.—On Dec. 20th, 1931, in a Birmingham nursing hom the wife of C. N. Chitnis, M.R.C.S., L.R.C.P., of a son.

COLLEY.—On Dec. 13th, 1931, the wife of R. Colley, M. Ch.B., D.O.M.S., of The Circus, Bath, of a son.

RICE.—On Dec. 26th, 1931, at Thorpe-road, Norwich, the wi of Dr. R. A. C. Rice, of a son.

MARRIAGES.

CRUICKSHANK—LOCKHART.—On Dec. 24th, 1931, at the Par Church, Great Shelford, near Cambridge, Douglas Barr Cruickshank, L.R.C.P. Edin., L.D.S., D.P.H. Cam to Hilda Joyce, third daughter of Mr. and Mrs. E. Lockhart, of Riversdale, Great Shelford.

DEATHS.

ALCOCK.—On Dec. 27th, 1931, George Herbert Alcock, M.R.C. L.R.C.P.

BIRD.—On Jan. 3rd, at 27, St. Peter's-road, St. Margaret's-o Thames, Tom Bird, M.A. Oxon., M.R.C.S., Anæsthetist Guy's Hospital 1881 to 1903, Consulting Anæsthetist sin 1903, aged 88 years.

BROWN.—On Jan. 3rd, suddenly, Joseph Norwood Brow M.D. Lond., of Finchley-road, N.W.

BROWN.—On Dec. 21st, 1931, at Mayfield, Hatch End, Andre Brown, M.D., M.R.C.P., in his 91st year.

CAREY.—On Dec. 31st, 1931, at Sausmarez House, Guernse Lieut.-Colonel John Thomas Carey, late R.A.M.C., ag 80 years.

HOLBECHE.—On Dec. 25th, 1931, at his residence, Priors Cr Malvern, Arthur Oliver Holbeche, M.R.C.S., &c., in 77th year.

HOLTON.—On Dec. 24th, 1931, suddenly, Francis William Par Holton, M.R.C.S., L.S.A., aged 74.

PITT.—On Jan. 1st, at Brandhoek, Gerrards Cross, Edwa Pitt, L.D.S., R.C.S. Eng.

THOMAS.—On Dec. 27th, 1931, at Welwyn, Herts, Dr. Benjam Wilfred Thomas, third son of the late Dr. Benjamin Thom of Llanelly.

WALKER.—On Dec. 27th, 1931, at Peterborough, Russ Ernest Walker, M.B., F.R.C.S.E.

WINTER.—On Dec. 24th, 1931, at The House that Jack Bui Wolverhampton, Walter Henry Trimnell Winter, M.R.C. L.R.C.P.I., son of the late G. W. Winter, of Ceylon.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices Births, Marriages and Deaths.

ADDRESSES AND ORIGINAL ARTICLES

SOME EFFECTS OF TRAUMA ON THE NERVOUS SYSTEM.*

BY C. M. HINDS-HOWELL, D.M. OXF., F.R.C.P. LOND.,
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL AND THE NATIONAL HOSPITAL, QUEEN-SQUARE.

INJURIES of the head take a prominent place among traumatic causes of nervous disorders, and it is worth while to study them in some detail. A severe blow on the head, whatever its origin, may produce the symptoms of concussion or of cerebral compression. It may cause no anatomical damage on the one hand, or on the other it may give rise to fracture of the skull, hæmorrhage, or contusion of the brain. Depressed fractures or perforating wounds may in addition cause laceration of the cerebral tissues.

Simple concussion results in loss of consciousness of a quite transient character. In any case where loss of consciousness is prolonged it is safe to assume that something more than simple concussion has occurred, and that there has at least been some contusion of the brain, with or without serious hæmorrhage. It is very important to recognise the site of this hæmorrhage. It may be extradural, e.g., when the middle meningeal artery is ruptured, subdural, or subarachnoid.

In *extradural hæmorrhage* with concussion the patient regains consciousness and there is then a period in which symptoms may be slight or non-existent. Where symptoms of concussion are absent there may at first be nothing to indicate anything serious; then after a longer or shorter period, known as the lucid interval, evidence of pressure appears, which may be manifest in focal symptoms alone, or progress with continuing hæmorrhage to the full picture of cerebral compression. Such symptoms are quite familiar: unconsciousness deepening into coma, bounding pulse, rising blood pressure, pupils usually dilated, and stertorous respiration. Death follows inevitably from respiratory failure unless relief from the compression is obtained.

The following case illustrates the effect of a small extradural hæmorrhage:—

A young man, aged 20, was playing cricket and while batting was hit on the left temple. He was not so seriously damaged at the time as to stop his innings, for he was able to resume it after a few minutes. The same evening he developed a severe headache and vomited. Two days later he had a typical Jacksonian fit limited to the right face. During the attack he was unable to speak. He consulted me about this and while in my room had a similar attack which lasted about five minutes. One could feel nothing on palpating the injured area, but at operation a fracture of the saucer variety was found and an extradural blood clot. The dura was opened but there was no subdural hæmorrhage and no evidence of contusion. I thought the patient, who made a good recovery after operation, was cured, but six months later he had two generalised epileptic fits. He was put on a course of bromide and remained free from further fits. I am sure the mistake I made in this case was the omission to put the patient on bromide directly after his operation, and in any similar condition I am sure that this would be a wise precaution.

In extradural hæmorrhage the lucid interval to which I have referred, when present, is very characteristic, and signs of a focal lesion in the brain are often present. It must be noted, however, that the lucid interval may be absent or of exceedingly short duration.

Jonathan Hutchinson described dilatation of the pupil as occurring on the homolateral side in the majority of cases of extradural hæmorrhage. That it may be seen at times is certain, but Bathe Rawling, in his book, the "Surgery of the Skull and Brain," states that in his cases the pupils were equally dilated in 46 per cent., constricted on the homolateral side in 36 per cent., and only dilated on the homolateral side in 18 per cent. Von Bergman's figures, quoted by Rawling, showed 30 per cent., with a Hutchinson pupil in 70 cases. In 56 per cent. both pupils were equally dilated.

Subdural and Subarachnoid Hæmorrhages.

When there is subdural or subarachnoid hæmorrhage the injury to the skull has nearly always been severe and there is often a fracture. The venous sinuses may be torn through, and hæmorrhage from superficial cerebral vessels may occur. The brain is often contused or lacerated as well. Under these circumstances the clinical picture is likely to differ materially from that of uncomplicated cases of extradural hæmorrhage.

As the blood usually diffuses freely through the subdural space focal symptoms are rare as compared with cases of extradural hæmorrhage, and symptoms of cerebral irritation and compression are early. The lucid interval which we have seen may be a characteristic of extradural hæmorrhage, is often absent or very short.

A very interesting condition is localised subdural hæmatoma. The cases in which this occurs are often those in which the head injury has appeared to be comparatively trivial. After the initial shock the patient seems to recover, but usually not completely. One is often told by relatives that the patient "never seemed to get quite right." But after a period varying from a few days to several weeks symptoms of a focal lesion begin to make their appearance, in addition to those of headache, irritability, giddiness, which may be already present. Gradually the symptoms of increasing cerebral compression develop, and unless they are relieved by operation the patient becomes comatose and dies.

The following case,[1] which was under my care and which was operated on by Mr. Paterson Ross at St. Bartholomew's, well illustrates several important points in connexion with this type of case.

A man, aged 64, was on August 23rd, 1927, knocked down by a bicycle. He was concussed and taken to the Royal Northern Hospital. He was detained but as he appeared quite well and no fracture of the skull was discovered, he was discharged a few days later. In mid-September he became lethargic and had difficulty in walking and by the end of September was unable to walk. On Oct. 10th he had an attack of vomiting with severe headache and thereafter became unable to feed himself. I saw him on this date and got him admitted under my care at St. Bartholomew's Hospital at once. His condition there varied from a semi-comatose state to complete consciousness and his physical signs varied as well. He had, however, a constant degree of right-sided hemiplegia with extensor plantar reflex on the right, flexor on the left. The leg was more affected than the arm.

On account of the long latent period a diagnosis of localised subdural hæmatoma was clearly established. Mr. Ross operated on the left side and found beneath a discoloured dura the typical blood clot, enclosed in its characteristic membrane, extending over almost the whole hemisphere. This he evacuated, finding the cortex depressed beneath it. Next day the patient was much more conscious and could move his right leg better than before operation. He relapsed, however, and again became unconscious 24 hours after the operation. In the belief that a further hæmorrhage had occurred the wound was reopened. No hæmorrhage was found, but it was noted that the depressed brain had not expanded. After this he gradually sank and died on the third day after operation. At the post-mortem a second and even larger hæmatoma was found on the opposite side of the brain. It was very remarkable that this second hæmatoma had seemingly caused no physical signs.

---

* A paper read before the Colchester Medical Society.

[1] Reported by J. P. Ross, St. Bart.'s Hosp. Rep., 1928, lxi., 112.

At that time I was unaware that the condition is frequently bilateral, but I now know that this is more often so than not. A small trephine opening should always be made on the opposite side, when the appearance of the dura will enable the presence or absence of a hæmatoma to be determined.

Injury of the brain tissue may take place without serious hæmorrhage, and usually on the side opposite to the site of injury. Coutrecoup is no doubt the explanation of this. Concussion followed by cerebral irritation and perhaps by symptoms of compression due to cerebral œdema is likely to occur. Paralysis may of course be present, depending on the site of the injury. *If so, it will come on immediately after* the injury, a fact which will serve to distinguish a primary brain lesion from an extra- or subdural hæmorrhage.

These cases of head injury present many difficult problems. The clear-cut difference between extra- and subdural hæmorrhage is commonly obscured owing to the presence of both, and the development of cerebral œdema may complicate the diagnosis where no hæmorrhage has taken place. Lumbar puncture should always be performed, for it may give important information in connexion with diagnosis, and is also a helpful therapeutic measure. Wherever there has been a considerable subarachnoid hæmorrhage the cerebro-spinal fluid will contain a large quantity of blood.

The pressure of the cerebro-spinal fluid should also be measured, for with increasing intracranial pressure the pressure of the cerebro-spinal fluid rises. The great danger in severe cases of head injury is from this increasing cerebral compression, due as often *to contusion and œdema of the brain as to hæmorrhage.* When the indications of a focal hæmorrhage are clear, and where it is impossible to combat the increasing compression by other measures, an operation should be undertaken. But I want particularly to emphasise the fact that cases in which there is a localised hæmorrhage which can be successfully treated by operation are few and far between. They are immensely outnumbered by those cases in which surgery, if attempted, is more likely to lead to disaster than to improvement. Careful nursing and the judicious use of such measures as lumbar puncture and the intravenous injections of hypertonic saline (30 c.cm. of a 30 per cent. solution) will usually prove more helpful than surgical intervention.

Speaking generally, it will be found that there is a number of factors which play an important part in the subsequent course of any particular case. Age is one of these. The young and the old are most liable to serious after-effects following severe injuries to the head. In the case of the young, mental development may be interfered with, whilst in the old, recuperative powers are heavily handicapped. The financial position of the patient is obviously another factor of great importance, for anxiety about the future and family responsibilities are bound to retard recovery, especially in patients of a worrying disposition.

Another most important factor is the immediate treatment which the patient receives. It is of the first importance that he should not be allowed to get up, nor return to work too soon. The medical attendant should err on the side of caution in thi If this precaution is not observed the probability of relapse associated with headache, irritability, and so on is greatly increased.

Remote Effects of Head Injury.

The remote effects of injury form a very important group, the more prominent members of which are paralysis, epilepsy, mental disorder ranging from insanity at one end of the scale, to impairment of memory and irritability of temper at the other, including also severe headache and the group of symptoms to which the unfortunate term traumatic neurasthenia has been applied. Let us examine some of these more closely.

TRAUMATIC EPILEPSY.

It is a well-established observation that epilepsy may be a sequel to severe head injuries. The attacks may be of the frankly Jacksonian type or they may *assume the guise of the common so*-called idiopathic variety, with grand mal and petit mal attacks. It is important to recognise also the epileptic equivalents such as vertigo, attacks of uncontrollable temper, memory lapses, and the like, to which Aldren Turner has called attention. These are likely to come on in the period between the injury and the manifestation of the fully developed epileptic attack. Vertigo is a symptom particularly common during this period, as has been pointed out by W. E. Stevenson.[2]

The period elapsing between the injury and the first fit varies very much. In my student days the opinion rather held the field that unless a fit occurred within a few months at most after the injury it could not properly be referred to the accident. But well recorded cases are not uncommon in which epileps has developed as long as 12 years after a gunsho wound of the head, and in which the patient has bee cured by the removal of the cicatrix. O. Foerste and W. Penfield[3] have recorded observations of grea interest in this connexion.

It is important to remember *that* injury to an *part* of the brain may cause epilepsy, and that th particular type of fit often gives the clue to the are which has been injured. I mention this because of case in which I was concerned which came into court

> The plaintiff, a bargee, *fell down the hold* of his barg He struck the back of his head and was picked up concusse There was a severe contusion over the occiput, but fracture of the skull was discovered. In the course of th next few weeks he had his first epileptic attack which wa followed by others. I advanced the view that the inju to his head was probably the cause of his fits. The doct who appeared for the defendants said that this wa impossible as it was well established that only injuries the motor cortex could give rise to epilepsy. The medic referee took the same view and the man lost his case.

Comment is needless but this incident is an examp among many others of the very unsatisfactory wa of medical referees and the absurdity of the prese state of affairs with regard to medical evidence compensation cases.

It is, as I have said, established that head injuri may give rise to epilepsy, but it is not so clear as what kind of injury is a necessary antecedent. W know that injuries to the brain which cause a cicatr are possible sources of epilepsy; so too are collectio of blood either subdural or extradural. Pressu from a depressed fracture is another possible caus The *cicatricial group* are likely to give fits after more or less long interval, the hæmorrhages ar foreign bodies (i.e., depressed bone) after a shorter on

---

[2] Brain, vol. liv., p. 214.
[3] Ibid., vol. lv., p. 99.

Can concussion with no evidence of gross damage the brain, fracture, or hæmorrhage act as an citant of epilepsy? The balance of opinion seems be that it can, but in such a case it seems likely at there is an individual predisposition to epilepsy. lcoholism is, I am sure, definitely a predisposing ndition. Severe emotional shock, which may be ssociated with the injury, may also be a factor in e development of epilepsy in a person predisposed y heredity, habits, or psychological constitution.

SO-CALLED TRAUMATIC NEURASTHENIA.

There is a number of symptoms commonly met with fter a severe head injury which may be the direct esult of the physical injury, or manifestations of eurasthenia, which I regard as being a psychological isorder. Such are headache, irritability, memory mpairment, difficulty in concentration, limitation of nental capacity, and so on. In trying to assess the ignificance of the symptoms, the severity of the njury, the patient's age, social position, and past ecord are all helpful.

The term traumatic neurasthenia has been given to this group of symptoms, and in my opinion most unfortunately. The name suggests that a definite disease has followed as the result of the injury, a particular type of neurasthenia peculiar to a person who has been injured. This is quite untrue. Traumatic neurasthenia differs in no way from any other kind of neurasthenia. Moreover, the development of this condition does not depend on the severity of the injury; it is, indeed, as likely to follow a minor injury, or no physical injury at all, as it is to supervene after serious physical disablement. If one carries one's mind back to the effect of injuries in the late war the very significant fact emerges that those who received a wound which from its severity took them away from the war for good rarely developed traumatic neurasthenia, whilst this was a common sequel to many much more trivial injuries.

So-called traumatic neurasthenia is rare except in those who are going to benefit from it. It usually takes some weeks to develop and in this latent period many psychological factors are at work; possibly ill-advised expressions of opinion by the doctor, the opinions of friends and sympathisers, the wholly criminal attentions of a certain class of touts offering legal aid, and the provisions of the Workmen's Compensation Act—all conspire to produce the condition. I am certain, if this Act had been limited to compensation for physical injuries and limited as to the duration period of the compensation, that traumatic neurasthenia would be a rare disorder.

The Spinal Cord.

I must now refer briefly to the effect of trauma on the spinal cord. Severe injuries causing fracture dislocations by direct violence are often followed by paraplegia. In most cases the cord is pulped by the damaged vertebra. There is complete motor paralysis, usually, in the early period after the injury, of a flaccid type with absence of tendon reflexes as the result of shock. The plantar reflexes may also be absent, but, if present, will be of the extensor type. There will be loss of all forms of sensation terminating in a sharply defined sensory level corresponding with the segment of the cord at the site of the injury. There will be retention of urine, an important point to remember since catheters must be passed at regular intervals or the bladder will become overdistended, a condition which adds to the risk of cystitis.

In dealing with such a case no operative interference should be contemplated until the period of shock has passed off. When this takes place improvement frequently occurs to a remarkable extent, unless the cord has been irretrievably damaged. Unfortunately regeneration of nerve-fibres does not take place within the spinal cord, probably because of the absence of the neurilemmal sheath which plays so prominent a part in the regeneration of peripheral nerves. Surgery can only remove any pressure which there may be on the cord from displaced bone, &c., One is always inclined to give the patient the slender chance of improvement which surgery holds out, but in my experience it is exceptional for any benefit to ensue from it.

Apart from damage as the result of direct injury, there may be hæmorrhage from indirect violence. This may be either external to or within the spinal cord. In the latter case a common site for such hæmorrhage is the cervical enlargement, when symptoms similar to those presented by a case of syringomyelia (at any rate from the motor and sensory aspect) are probable. Hæmorrhage chiefly outside the cord will usually give rise to weakness, from pressure on the anterior roots, and pain, from irritation of the posterior roots. Possibly concussion of the cord may add its part to the clinical picture, though this is more speculative.

The following case is illustrative of the symptoms following a fall from a polo pony:—

On April 12th an officer had a "crash" when playing polo. He was more or less unconsciousness for 12 hours, so he evidently sustained some cerebral contusion. On recovering consciousness both arms were completely paralysed, but he could move his legs. Both arms were painful and extremely hyperæsthetic. There was no loss of sphincter control. He was kept in bed for three weeks by which time there was some return of power in both arms, but he was still unable to shave.

I saw him three months after his accident. He complained of stiffness in movements of his neck, but no fracture had been detected. His arms had recovered a considerable degree of power but flexion and extension of the elbow were very poorly performed, especially on the left side. There was still hyperæsthesia in both arms. Sometimes when bending his neck or coughing or sneezing he would get widespread paræsthesia all over his body below his neck. The arm reflexes were brisk, abdominal reflexes present, knee- and ankle-jerks very brisk, ankle-clonus and extensor plantar reflexes on both sides. There were no headaches or other cerebral symptoms.

He ultimately made a complete recovery and was able to remain on the active list. In this case there must have been hæmorrhage outside the cord in the cervical region which produced pressure effects at that level. The symptoms of root irritation were very marked.

CIRCUMSCRIBED SEROUS MENINGITIS.

There are cases in which an injury to the spine, which may at the time appear comparatively trivial, ultimately gives rise to a slowly progressive paraplegia. Sir Victor Horsley many years ago first drew attention to this possibility, to which the name meningitis serosa circumscripta has been given. It is a condition in which adhesions appear to form in the subarachnoid space, as the result of which the cerebro-spinal fluid becomes collected in a cyst-like manner. I have always found it difficult to understand the exact mechanism of this as it is, I think, remarkable that under these circumstances a fluid cyst with increasing pressure should form.

The appearances at operation are very characteristic, as the dura is found to be tense and the subarachnoid space distended with fluid compressing the cord. As soon as the arachnoid is punctured the fluid escapes with a gush and thereafter the symptoms of compression of the cord are relieved.

A case of the kind which I had under my care was that of a boy aged about 20 who fell backwards over the back of operation. In the belief that a further hæmorrhage had occurred the wound was reopened. No hæmorrhage was found, but it was noted that the depressed brain had not expanded. After this he gradually sank and died on the third day after operation. At the post-mortem a second and even larger hæmatoma was found on the opposite side of the brain. It was very remarkable that this second hæmatoma had seemingly caused no physical signs.

At that time I was unaware that the condition is frequently bilateral, but I now know that this is more often so than not. A small trephine opening should always be made on the opposite side, when the appearance of the dura will enable the presence or absence of a hæmatoma to be determined.

Injury of the brain tissue may take place without serious hæmorrhage, and usually on the side opposite to the site of injury. Coutrecoup is no doubt the explanation of this. Concussion followed by cerebral irritation and perhaps by symptoms of compression due to cerebral œdema is likely to occur. Paralysis may of course be present, depending on the site of the injury. If so, it will come on immediately after the injury, a fact which will serve to distinguish a primary brain lesion from an extra- or subdural hæmorrhage.

These cases of head injury present many difficult problems. The clear-cut difference between extra- and subdural hæmorrhage is commonly obscured owing to the presence of both, and the development of cerebral œdema may complicate the diagnosis where no hæmorrhage has taken place. Lumbar puncture should always be performed, for it may give important information in connexion with diagnosis, and is also a helpful therapeutic measure. Wherever there has been a considerable subarachnoid hæmorrhage the cerebro-spinal fluid will contain a large quantity of blood.

The pressure of the cerebro-spinal fluid should also be measured, for with increasing intracranial pressure the pressure of the cerebro-spinal fluid rises. The great danger in severe cases of head injury is from this increasing cerebral compression, due as often to contusion and œdema of the brain as to hæmorrhage. When the indications of a focal hæmorrhage are clear, and where it is impossible to combat the increasing compression by other measures, an operation should be undertaken. But I want particularly to emphasise the fact that cases in which there is a localised hæmorrhage which can be successfully treated by operation are few and far between. They are immensely outnumbered by those cases in which surgery, if attempted, is more likely to lead to disaster than to improvement. Careful nursing and the judicious use of such measures as lumbar puncture and the intravenous injections of hypertonic saline (30 c.cm. of a 30 per cent. solution) will usually prove more helpful than surgical intervention.

Speaking generally, it will be found that there is a number of factors which play an important part in the subsequent course of any particular case. Age is one of these. The young and the old are most liable to serious after-effects following severe injuries to the head. In the case of the young, mental development may be interfered with, whilst in the old, recuperative powers are heavily handicapped. The financial position of the patient is obviously another factor of great importance, for anxiety about the future and family responsibilities are bound to retard recovery, especially in patients of a worrying disposition.

Another most important factor is the immediate treatment which the patient receives. It is of the first importance that he should not be allowed to get up, nor return to work too soon. The medical attendant should err on the side of caution in this. If this precaution is not observed the probability of relapse associated with headache, irritability, and so on is greatly increased.

Remote Effects of Head Injury.

The remote effects of injury form a very important group, the more prominent members of which are paralysis, epilepsy, mental disorder ranging from insanity at one end of the scale, to impairment of memory and irritability of temper at the other, including also severe headache and the group of symptoms to which the unfortunate term traumatic neurasthenia has been applied. Let us examine some of these more closely.

TRAUMATIC EPILEPSY.

It is a well-established observation that epilepsy may be a sequel to severe head injuries. The attacks may be of the frankly Jacksonian type or they may assume the guise of the common so-called idiopathic variety, with grand mal and petit mal attacks. It is important to recognise also the epileptic equivalents such as vertigo, attacks of uncontrollable temper, memory lapses, and the like, to which Aldren Turner has called attention. These are likely to come on in the period between the injury and the manifestation of the fully developed epileptic attack. Vertigo is a symptom particularly common during this period, as has been pointed out by W. E. Stevenson.[2]

The period elapsing between the injury and the first fit varies very much. In my student days the opinion rather held the field that unless a fit occurred within a few months at most after the injury it could not properly be referred to the accident. But well-recorded cases are not uncommon in which epilepsy has developed as long as 12 years after a gunshot wound of the head, and in which the patient has been cured by the removal of the cicatrix. O. Foerster and W. Penfield[3] have recorded observations of great interest in this connexion.

It is important to remember that injury to *any part* of the brain may cause epilepsy, and that the particular type of fit often gives the clue to the area which has been injured. I mention this because of a case in which I was concerned which came into court

> The plaintiff, a bargee, fell down the hold of his barge He struck the back of his head and was picked up concussed There was a severe contusion over the occiput, but n fracture of the skull was discovered. In the course of th next few weeks he had his first epileptic attack which wa followed by others. I advanced the view that the injur to his head was probably the cause of his fits. The docto who appeared for the defendants said that this wa impossible as it was well established that only injuries t the motor cortex could give rise to epilepsy. The medica referee took the same view and the man lost his case.

Comment is needless but this incident is an exampl among many others of the very unsatisfactory way of medical referees and the absurdity of the presen state of affairs with regard to medical evidence i compensation cases.

It is, as I have said, established that head injuri may give rise to epilepsy, but it is not so clear as t what kind of injury is a necessary antecedent. W know that injuries to the brain which cause a cicatri are possible sources of epilepsy; so too are collectio of blood either subdural or extradural. Pressu from a depressed fracture is another possible caus The cicatricial group are likely to give fits after more or less long interval, the hæmorrhages an foreign bodies (i.e., depressed bone) after a shorter on

---

[2] Brain, vol. liv., p. 214.

[3] Ibid., vol. lv., p. 99.

Can concussion with no evidence of gross damage the brain, fracture, or hæmorrhage act as an xcitant of epilepsy ? The balance of opinion seems be that it can, but in such a case it seems likely hat there is an individual predisposition to epilepsy. lcoholism is, I am sure, definitely a predisposing ondition. Severe emotional shock, which may be ssociated with the injury, may also be a factor in he development of epilepsy in a person predisposed y heredity, habits, or psychological constitution.

SO-CALLED TRAUMATIC NEURASTHENIA.

There is a number of symptoms commonly met with fter a severe head injury which may be the direct esult of the physical injury, or manifestations of eurasthenia, which I regard as being a psychological isorder. Such are headache, irritability, memory impairment, difficulty in concentration, limitation of mental capacity, and so on. In trying to assess the significance of the symptoms, the severity of the injury, the patient's age, social position, and past record are all helpful.

The term traumatic neurasthenia has been given to this group of symptoms, and in my opinion most unfortunately. The name suggests that a definite disease has followed as the result of the injury, a particular type of neurasthenia peculiar to a person who has been injured. This is quite untrue. Traumatic neurasthenia differs in no way from any other kind of neurasthenia. Moreover, the development of this condition does not depend on the severity of the injury; it is, indeed, as likely to follow a minor injury, or no physical injury at all, as it is to supervene after serious physical disablement. If one carries one's mind back to the effect of injuries in the late war the very significant fact emerges that those who received a wound which from its severity took them away from the war for good rarely developed traumatic neurasthenia, whilst this was a common sequel to many much more trivial injuries.

So-called traumatic neurasthenia is rare except in those who are going to benefit from it. It usually takes some weeks to develop and in this latent period many psychological factors are at work; possibly ill-advised expressions of opinion by the doctor, the opinions of friends and sympathisers, the wholly criminal attentions of a certain class of touts offering legal aid, and the provisions of the Workmen's Compensation Act—all conspire to produce the condition. I am certain, if this Act had been limited to compensation for physical injuries and limited as to the duration period of the compensation, that traumatic neurasthenia would be a rare disorder.

The Spinal Cord.

I must now refer briefly to the effect of trauma on the spinal cord. Severe injuries causing fracture dislocations by direct violence are often followed by paraplegia. In most cases the cord is pulped by the damaged vertebra. There is complete motor paralysis, usually, in the early period after the injury, of a flaccid type with absence of tendon reflexes as the result of shock. The plantar reflexes may also be absent, but, if present, will be of the extensor type. There will be loss of all forms of sensation terminating in a sharply defined sensory level corresponding with the segment of the cord at the site of the injury. There will be retention of urine, an important point to remember since catheters must be passed at regular intervals or the bladder will become overdistended, a condition which adds to the risk of cystitis.

In dealing with such a case no operative interference should be contemplated until the period of shock has passed off. When this takes place improvement frequently occurs to a remarkable extent, unless the cord has been irretrievably damaged. Unfortunately regeneration of nerve-fibres does not take place within the spinal cord, probably because of the absence of the neurilemmal sheath which plays so prominent a part in the regeneration of peripheral nerves. Surgery can only remove any pressure which there may be on the cord from displaced bone, &c., One is always inclined to give the patient the slender chance of improvement which surgery holds out, but in my experience it is exceptional for any benefit to ensue from it.

Apart from damage as the result of direct injury, there may be hæmorrhage from indirect violence. This may be either external to or within the spinal cord. In the latter case a common site for such hæmorrhage is the cervical enlargement, when symptoms similar to those presented by a case of syringomyelia (at any rate from the motor and sensory aspect) are probable. Hæmorrhage chiefly outside the cord will usually give rise to weakness, from pressure on the anterior roots, and pain, from irritation of the posterior roots. Possibly concussion of the cord may add its part to the clinical picture, though this is more speculative.

The following case is illustrative of the symptoms following a fall from a polo pony :—

On April 12th an officer had a " crash " when playing polo. He was more or less unconsciousness for 12 hours, so he evidently sustained some cerebral contusion. On recovering consciousness both arms were completely paralysed, but he could move his legs. Both arms were painful and extremely hyperæsthetic. There was no loss of sphincter control. He was kept in bed for three weeks by which time there was some return of power in both arms, but he was still unable to shave.

I saw him three months after his accident. He complained of stiffness in movements of his neck, but no fracture had been detected. His arms had recovered a considerable degree of power but flexion and extension of the elbow were very poorly performed, especially on the left side. There was still hyperæsthesia in both arms. Sometimes when bending his neck or coughing or sneezing he would get widespread paræsthesia all over his body below his neck. The arm reflexes were brisk, abdominal reflexes present, knee- and ankle-jerks very brisk, ankle-clonus and extensor plantar reflexes on both sides. There were no headaches or other cerebral symptoms.

He ultimately made a complete recovery and was able to remain on the active list. In this case there must have been hæmorrhage outside the cord in the cervical region which produced pressure effects at that level. The symptoms of root irritation were very marked.

CIRCUMSCRIBED SEROUS MENINGITIS.

There are cases in which an injury to the spine, which may at the time appear comparatively trivial, ultimately gives rise to a slowly progressive paraplegia. Sir Victor Horsley many years ago first drew attention to this possibility, to which the name meningitis serosa circumscripta has been given. It is a condition in which adhesions appear to form in the subarachnoid space, as the result of which the cerebro-spinal fluid becomes collected in a cyst-like manner. I have always found it difficult to understand the exact mechanism of this as it is, I think, remarkable that under these circumstances a fluid cyst with increasing pressure should form.

The appearances at operation are very characteristic, as the dura is found to be tense and the subarachnoid space distended with fluid compressing the cord. As soon as the arachnoid is punctured the fluid escapes with a gush and thereafter the symptoms of compression of the cord are relieved.

A case of the kind which I had under my care was that of a boy aged about 20 who fell backwards over the back of a seat. He ricked his back at the time but was not laid up with it though he complained of severe pain for some days. About nine months afterwards he began to experience progressive disability in his legs, and ultimately developed a definite paraplegia with a sensory level, but without complete loss of sensation below this level. At operation a condition of affairs similar to that to which I have referred was found, and the boy ultimately made a good recovery.

INJURIES OF PLEXUSES.

The brachial plexus from its position is peculiarly liable to injury and it is exposed to risk very early in life. The danger to it is well known in cases of transverse presentation with a prolapsed arm. In such cases the upper roots of the plexus (C. 5, 6, and 7) are those chiefly exposed to injury and the lower roots from their more protected position are less likely to suffer.

A grave danger in cases of severe injury, for example from a fall, is that the roots may be torn out of the cord. This seems more likely to happen than rupture of the cords of the plexus itself. The first case which I saw of this impressed me very much.

A farmer weighing 16 st. was returning from market where he had certainly had some alcoholic refreshment. He was driving a dog-cart and fell out of this on to the road. The right side of his head and his right shoulder appear to have shared the force of his fall. His right arm was completely paralysed at first, flaccid, with absent reflexes and complete loss of sensation. Gradually the muscles supplied by the lower roots recovered, but there was absolutely no recovery in those supplied by the fifth, sixth, and seventh cervical roots. An exploratory operation was performed, and it was found that these roots had been torn out of the cord. An attempt was made to graft the damaged roots into the lower cords of the plexus, but without success.

Unless the cords of the plexus are ruptured or evulsed recovery follows in due course after injury, and this fortunately is the more common experience. As an example a man came under my care who had been injured in a rather unusual way.

He had taken two mastiffs for a walk, each on a separate lead. The mastiffs saw a cat and gave chase, taking their leader with them. They came on a lamp-post, one dog passing it on either side, and the unfortunate man, still holding on to his obstreperous charges, struck the lamp-post with the root of his neck. Paralysis of the upper brachial plexus type supervened, from which he recovered without operation.

The lumbo-sacral plexus is much less exposed to direct injury than the brachial plexus. There is an interesting though fortunately rare condition in which the lumbo-sacral cord sustains damage in the mother during childbirth. I have seen several such cases and wrote a short account of three in the *St. Bartholomew's Hospital Reports* for 1908. Within a few days following confinement the patient complains of severe pains in her leg, the particular leg affected depending probably on the position of the fœtus. The labour is likely to have been difficult and prolonged. There follows almost at once paralysis of the muscles supplied by the external popliteal nerve, whilst those supplied by the internal popliteal are affected to a much less extent. As a result there is foot-drop with loss of eversion of the foot, whilst plantar flexion is weak. The knee-jerk is brisker than on the sound side; the ankle and plantar reflexes are absent. Flexion of the knee may be weak, extension is well performed. Some sensory loss is present in the area of the fourth and fifth lumbar roots and the first sacral. In the cases I have observed improvement has taken place but recovery has never been complete. The delay between delivery and the development of symptoms (i.e., from two to nine days) suggests that some other factor besides trauma must play a part. This may be an inflammation, but in the cases I have observed there has been no rise of temperature and no evident sepsis.

General Nervous Disorders.

I will now pass on to consider trauma as it may affect certain general disorders of the nervous system.

There is, I am sure, no doubt that an injury may be the determining factor in the development of symptoms of latent organic disease. Thus the symptoms of syphilis of the nervous system may undoubtedly be unmasked by physical injury or shock.

Some years ago I was asked to give evidence in Court in a case which was brought by the driver of a horse 'bus against his employer. The man had been in regular work and apparently in good health until he was thrown from his box to the ground by his horse starting before he was securely seated. He was very much shaken by this and was taken home. He remained in bed for two or three days and when he got up was very unsteady on his legs. Examination showed a fully developed picture of tabes dorsalis. The case came into Court and I pointed out that the cause of tabes was something quite different from a fall off a 'bus. A very junior doctor who appeared for the plaintiff read a passage from Osler in which it was stated that trauma was an occasional cause of tabes. The 'bus driver won his case and certainly the joke was against me for the doctor for the plaintiff who had quoted Osler with so much success had just completed his time as my house physician.

Now although no amount of falls from 'buses will give anyone tabes dorsalis, it is certain that such an accident may precipitate the development of symptoms. In a similar way I have had more than one case in which the symptoms of general paralysis have developed following the shock of injury—not necessarily a head injury.

Another type of case in which injury may at any rate precipitate the development of symptoms is paralysis agitans.

A man, aged 52, a carpenter, was at work on a building and fell through a ceiling, sustaining a bad fracture of the humerus. It was set in a bad position in the first instance and had to be broken down and reset at St. Bartholomew's Hospital. As the time for this man's discharge approached I was asked to see him as he had developed a tremor. I found him with well-marked signs of paralysis agitans, already so severe as to prevent him resuming his employment. Before his accident he had no symptoms whatever of the disease. The conclusion is, I submit, irresistible, that the shock of his accident, mental and physical as it had been, was responsible for the development of his symptoms.

The evidence is not so clear in the case of such a disease as amyotrophic lateral sclerosis. This is fortunately not very common, but anyone who goes carefully into the history of these cases will find in a certain number of them a history of physical shock of some kind. We do not know anything very definite with regard to the ætiology of this disease, and Gowers's view of "abiotrophy"—an inherent lack of vitality in the motor cells of the cortex and spinal cord—has at least not been disproved. It is at any rate intelligible that a shock to the nervous system may prejudice the vitality of cells in which the vital spark is already burning low.

MEMORIAL TO A BELFAST PHYSICIAN.—Last week a memorial tablet to the late Dr. H. L. McKisack was unveiled at the entrance to one of the wards of the Royal Victoria Hospital, Belfast. The tablet bears the following inscription:—"To Henry Lawrence McKisack, M.D., F.R.C.P.—1859-1928—who gave his services to this Hospital from 1895 to 1924, and in his labours here, and beyond these walls, won the affection and gratitude of many." A sum of £618 has been subscribed to form the nucleus of a fund for original research in medicine and surgery.

OBSERVATIONS ON THE USE OF NEMBUTAL AND CHLORAL IN CHILDBIRTH.

By James Vincent O'Sullivan, M.D. N.U.I.,
M.R.C.P. Lond., F.R.C.S. Eng.,
OBSTETRIC REGISTRAR AND FIRST ASSISTANT, LONDON HOSPITAL;
AND
W. W. Craner, M.B. Lond.,
LATE RESIDENT ACCOUCHEUR AT THE HOSPITAL.

The use of sedative drugs to relieve the pains of labour has long been of universal interest. Many drugs and combinations of drugs have been tried but none has yet been widely accepted.

Chloral was introduced as a mild hypnotic by Oscar Liebreich in 1869. It has been used extensively for its sedative effects but given alone it does not produce a painless labour. The morphia and scopolamine combination was introduced by von Schneiderlin in 1899; it was used in midwifery by von Steinbuchel in 1902 in the first determined attempt to produce a painless labour and was popularised by the publication of a large series of cases by C. J. Gauss (1906). In the opinion of many, however, the disadvantages of this combination outweigh the advantages. The method introduced by J. T. Gwathmey has been successful in the hands of experts.[1] Avertin does not produce a painless labour, because its action seldom lasts more than one and a half hours (J. M. Connell [2]). Paraldehyde was tried recently by one of us (J. V. O'S.). It was given rectally in doses of up to one drachm to the stone weight of the patient. The best time to administer the drug was when the os uteri was between two-fifths to three-fifths dilated in primiparæ and when labour had started in multiparæ. The drug was always freshly prepared before use, but even so was too irritating to be given undiluted. At first the paraldehyde was diluted with ten times its own quantity of water, but in this case the bulk was too great to allow of a sufficient dose to be given. Next the drug was diluted 1 in 3 with olive oil. Though a few successes were obtained paraldehyde by rectal administration was given up in favour of nembutal and chloral, because in the majority of cases the drug acted as an enema and this tendency could not be satisfactorily overcome. Recently barbiturates have been used by various workers as analgesics in midwifery, but the results to date are conflicting. Nembutal [3] has been given by the mouth, but we can find no report of its routine administration in childbirth.

We have experimented with a combination of nembutal and chloral given by the mouth. This innovation was undertaken because, in the opinion of many, there was not a suitable combination of drugs which could be given with ease in general practice to women in labour. The combination of nembutal and chloral for oral administration has not, to our knowledge, been used before as a method of relieving the pains of labour. We present the records of 60 consecutive cases treated at the London Hospital in the wards of Mr. Eardley Holland and Mr. Victor Lack. It is our opinion that the results obtained show many advantages over the existing forms of analgesia in midwifery.

Nembutal is a recently introduced barbituric acid derivative (sodium-ethyl-methyl-butyl barbiturate) which hydrolyses on keeping, and is therefore put up in gelatin-coated capsules (grs. 1½ in each). It has the characteristic hypnotic properties of barbiturates though, as nembutal is rapidly excreted, the sleep is shorter than that produced by many others. Recovery from the drug takes place in about four hours. Nembutal is said to cause restlessness less often than other barbiturates.

Chloral hydrate is well known as a hypnotic. We gave it in grs. 30 doses in 3 oz. of freshly prepared home-made lemonade sweetened with three to four teaspoonfuls of sugar. This was necessary to overcome the bitter and unpalatable taste of the drug.

Method of Administration.

Selection of cases.—In our series of 60 consecutive cases we found no contra-indications. The combination of nembutal and chloral was given successfully in cases of test labour and in cases complicated by heart disease and albuminuria.

Environment.—Routine examination of the patient should precede the administration of the drug. The room should be dimly lighted and quiet. A nurse should be in constant attendance, although many of our patients were left unattended from periods varying from 15 to 30 minutes.

Time of administration.—The initial dose should be given to a primipara when the os uteri is two-fifths to three-fifths dilated and pains are occurring regularly; and to a multipara when the os is one-fifth to two-fifths dilated and regular pains are present. The drugs are to be given by the mouth only. A total dose of nembutal grs. 7½ and chloral hydrate grs. 120 should not be exceeded in 12 hours. This total is reached by repeated single doses as follows: an initial dose of nembutal grs. 3 and chloral hydrate grs. 30; subsequent doses of nembutal grs. 1½ and chloral hydrate grs. 30. These drugs are not given simultaneously. The nembutal should always precede the chloral by ten minutes, because a lesser interval may excite vomiting. The first "repeat" dose is given two hours after the initial dose. Subsequent doses are given every three hours. The interval between doses should never exceed four hours; for when this period is exceeded amnesia is never complete.

Heart cases.—In heart cases to prevent the possibility of restlessness we advise that morphia gr. 1/8 be given hypodermically with the initial dose. The dose of morphia should not be repeated.

DIFFICULTIES.

The initial difficulties we met with may be described under the headings of dosage, vomiting, restlessness, and precautions.

Dosage.—As we did not know the power of the drugs and feared the effects on the mother and fœtus, we began by administering small amounts (an initial dose of nembutal grs. 1½ and chloral grs. 15) and incomplete amnesia resulted. Subsequently we increased the initial dose to nembutal grs. 4½ and chloral grs. 30, but found that this diminished the force and frequency of the uterine contractions. By experiment we found that the best initial dose was nembutal grs. 3 and chloral grs. 30. Too early administration tends to slow down labour. Labour actually came to a complete standstill for 24 hours in a primipara to whom the drugs had been given as soon as pains had begun. Too late administration—e.g., an hour and a half before delivery—did not give the drugs time to act fully, and the four cases classified as failures come under this heading. The time interval between doses also had to be found. Our aim was to produce a continuous amnesia. With the doses given as above we found that if the interval exceeded four hours, interruption of amnesia resulted. The best interval for the first "repeat" dose was found by experiment to be two hours; for subsequent doses every three hours.

[3] Brit. Med. Jour., 1931, i., 358; THE LANCET, 1931, i., 74 and 586; Proc. Roy. Soc. Med. (Sect. Anæsth.), 1930, ix. 210.

Vomiting occurred in our early cases and immediately followed the ingestion of the drugs. There was no vomiting when nembutal was taken alone, and it was prevented, firstly, by giving the drugs separately (eventually we found that a ten-minute interval sufficed) and secondly, by giving the chloral in smaller bulk, making it more palatable and causing the patient to sip it slowly.

Restlessness was noted in varying degree in 12 of our 60 cases. In ten the restlessness was slight. In two it was severe. One of these was a case of heart disease, in the other labour was normal. No patient became maniacal. Restlessness developed, either shortly after the administration before the full effects of the drugs had been established, or during the stages of recovery from the effects of the drug, if the patient was still in strong labour. In the former group no prevention was necessary as the excitement was always slight. In the latter group, if early in the second stage, the drugs were repeated in the doses recommended, or, if the head was crowning, a few whiffs of chloroform from a Junker's inhaler were given. Morphia gr. 1/12 to 1/6 was given in ten cases. Three of these were cases of heart disease, and it was given to prevent possible restlessness. In four it was given late in labour with the initial dose of nembutal and chloral. The remaining three were cases of prolonged test labour. Of the ten labours five were painless. In no case did restlessness occur after labour was completed.

Precautions.—No precautions were taken in our cases to exclude external sensory impulses. As a general rule the ward was not darkened, nor were the patients isolated apart from a screen around the bed. This procedure was unavoidable because of restricted accommodation. The labour ward was, of course, kept as quiet as possible, but this was difficult, because on many occasions two or three patients were in labour at the same time.

Clinical Effects of the Drugs.

The first effect of the drugs was a sensation of drowsiness which was followed by sleep. All the patients slept for varying periods after taking the drugs. Some awakened with the pains whilst others were only roused, and a few did not even move with the pains. Some patients were roused easily and could be made to talk and answer simple questions rationally though slowly. These patients usually had "islands of memory." Other patients were roused with difficulty, would answer questions very slowly, and then drop back to sleep whilst being questioned. A third group (two cases) could not be roused to answer any questions. These last two groups had no islands of memory. Only four patients were noisy and then only with the pains. Most patients slept for times varying from one to eight hours after delivery and awakened fresh and well. Respiration did not change in rate or depth. There was only one case of slight cyanosis, the cause of which we could not discover.

Cardiovascular system.—The pulse-rate did not alter. The blood pressure showed only slight variations between 5 and 10 mm. except in one case where it fell 25 mm. In this case the fall took place 15 minutes after the administration of the drug. The patient showed no signs of collapse or distress, and in an hour the pressure had regained its normal height.

Urinary system.—We had no case of retention or any other urinary trouble. This contrasts favourably with the morphia and scopolamine narcosis in which there is a tendency to retention.

Alimentary system.—The patients had no trouble with their bowels, and did not vomit at any time after delivery, nor had they any digestive upsets during the puerperium.

Central nervous system.—The pupils usually remained moderately dilated and reacted to light and accommodation. The conjunctival reflex was absent in several of our patients, and in two the corneal reflex was also absent. In four cases the patient had coarse nystagmoid movements on lateral fixation the following day, but these passed off within 12 hours. One patient had double vision for five hours. There were no other ocular disturbances. The tendon reflexes varied. In most cases they were unaltered, in some cases they were slightly increased or diminished, and in two cases they were absent. All reflexes returned when the patient awakened after delivery. Muscle tone, as a rule, was not interfered with, but in two cases the limb muscles were flaccid.

EFFECTS ON LABOUR.

First stage.—In 60 per cent. of our cases there was no lengthening of this stage. In the remaining 40 per cent. it was slightly prolonged but never excessively. It is interesting to note that in three cases of primary uterine inertia the pains were definitely stimulated in force and frequency after the drugs were administered.

Second stage.—In 50 per cent. of our cases there was no apparent lengthening of this stage. Labour advanced normally and the patient was able to bear down with the pains. In the other 50 per cent. there was a slight lengthening, and the bearing-down efforts were impaired. The average time of the second stage in the primipara was 2 hours and 36 minutes, in the multipara 1 hour and 30 minutes. In 20 cases we gave chloroform only with the crowning of the head. Of these 20 cases 13 were painless labours. Chloroform can be given by Junker's inhaler (the method we used) by the drop method, or in ampoules. From an analysis of our cases we note that forceps delivery was used in ten (one multipara and nine primiparæ). In two of these cases the use of forceps was indicated because th[illegible] patients had rheumatic valvular disease of the heart, and in three others to terminate test labours, one of which we shall describe below (Case 3). In the remaining five cases forceps were applied for delay in the second stage, two of these being for unrotated posterior positions. A general anæsthetic of either gas-and-oxygen or ether was given in all ten cases. Pituitrin was given in two cases where the head was delayed at the vulva.

During the last two and a half years the forceps rate at the London Hospital was 13·4 per cent. In our 60 cases it was 16·6 per cent.

Third stage.—There was no prolongation, the average time being 17 minutes. In 54 cases the placenta was expelled spontaneously or expressed from the vagina without any excessive bleeding. Post-partum hæmorrhage occurred in six cases. Five of these were mild (average loss 15 to 20 oz.), one was severe (loss 30 to 40 oz.). Of the five mild cases three were immediate, two were delayed. In the two delayed cases the hæmorrhage occurred two to three hours after delivery. All the mild cases were controlled by fundal pressure and an injection of pituitrin and ergot. In the severe case there was a bicornuate uterus and a bipartite placenta which separated incompletely, one part remaining in the uterus and the other in the vagina.

EFFECTS ON THE FŒTUS AND PUERPERIUM.

We have given nembutal and chloral in 60 cases, many of them difficult labours, and in no case have we had a dead child. The babies in all but six cases were born healthy and of good colour, and cried lustily. Four of these six infants were born in apnœa and two in white asphyxia. The latter two were born in test labours. Two of the former had morphia. In all of these cases regular breathing was established within ten minutes.

The puerperium was normal in all but one case in which parametritis occurred. The milk flow was never disturbed and the babies throve during their stay in hospital.

Results.

The standard by which we determined our results was based on the statements made by the patients when questioned on the day after labour. These results were as follows:—

(*a*) Painless labour..	..	37	cases	....	62 per cent.
(*b*) Very good result	..	13	„	....	21 „
(*c*) Good result	.. ..	6	„	....	10 „
(*d*) Failure	.. ..	4	„	....	7 „
		—			—
Total	.. ..	60	„	....	100 „

(*a*) Complete amnesia. (*b*) Very good results when the patient had vague recollection of a few incidents, such as the birth of the head. Many of these labours would undoubtedly have been completely painless if chloroform had been given during the birth of the head. (*c*) Good results, in which partial amnesia was present and when the intensity of the pains was diminished. (*d*) Failures, when the patient slept in the intervals between pains but remembered all her labour.

The following are examples to illustrate our results:—

CASE 1. *Painless labour.*—Aged 31. Three previous labours. Treatment was started when the os uteri was one-fifth to two-fifths dilated and the uterus was contracting regularly. The duration of the labour from the time of the giving of the drug was 8¼ hours. Nembutal grs. 6 and chloral grs. 90 were given during this period. The first stage lasted 9½ hours and the second stage ¾ hour. The third state lasted 20 minutes. No post-partum hæmorrhage occurred. No restlessness. No choloroform was given. The baby was born healthy ahd cried at once. When asked the following day about her labour the patient could recollect nothing after taking the first dose of the drug.

CASE 2. *Painless labour.*—Aged 26. One previous labour. A case of twins. Treatment started when the os was two-fifths and regular pains were occurring. The initial doses of nembutal grs. 3 and chloral hydrate grs. 30 were given. Three "repeat" doses of nembutal grs. 1½ and chloral hydrate grs. 30 were administered. Patient slept between the pains. There was no restlessness. The first stage lasted 14 hours. The second stage lasted ¾ hour. Both babies were breech deliveries. Both babies were healthy and cried at once. There was no post-partum hæmorrhage. The total duration of labour from the time of the administration of the drugs was 10¼ hours. This patient awakened eight hours after her delivery, put her hand on her abdomen and said, "where are my babies?" She did not remember anything of her labour after the first dose.

CASE 3. *Painless labour.*—Aged 23. Primipara. Test labour at term. Small round pelvis. On Nov. 14th patient was examined under an anæsthetic and though there was slight overlap of the fœtal head it was thought that the head would mould through the pelvis. Surgical induction by pig's bladder at 8 P.M. was followed by some pains in a few hours. The next day the bladder was removed from the vagina and the os was found to be four-fifths. On Nov. 16th at 5 P.M. patient began to have definite pains. At 8 P.M. the pains were occurring 1 in every 5 minutes. Nembutal grs. 3 and chloral hydrate grs. 30 were given. At 10 P.M. morphia gr. 1/6 was injected to ensure deep sleep. On the 17th at 4 A.M. the os was full. Pains were moderate in force. The baby's head was still high but was slowly moulding through. The patient was sleeping soundly between pains. At 8.30 A.M. nembutal grs. 3 was given to the patient. At 1.30 nembutal grs. 1½ and chloral grs. 30 were given. At 2.30 P.M. patient was flaccid. There was no corneal reflex present. The uterus was contracting regularly. At 4 P.M. a mid forceps delivery was performed under gas and oxygen. The child was limp and feeble at first but recovered fully in 10 minutes. The third stage was completed in 15 minutes. There was no post-partum hæmorrhage. The total drugs given in this case were nembutal grs. 9, chloral hydrate grs. 90, and morphia gr. 1/6. Labour was completed 20 hours after the administration of the drug. The second stage lasted 12 hours. Next day the patient remembered nothing about her labour after the giving of the drugs. The patient had a normal puerperium and the baby was in excellent health on discharge from hospital three weeks after delivery.

CASE 4. *Very good result.*—Aged 29. Primipara. Labour lasted 17 hours. Total doses nembutal grs. 6 and chloral grs. 60. The first dose was given when the os uteri was three-fifths dilated. Patient slept soon after the administration of the drug. Patient remembered vaguely the pains towards the end of her labour but did not remember the birth of the head. She remembered a stitch being inserted into the perineum.

CASE 5. *Good result.*—Primipara. The drugs were given when the os uteri was three-fifths dilated. The total dose given was nembutal grs. 6 and chloral hydrate grs. 60 and chloroform during the birth of the head. There was no restlessness. The second stage lasted one hour and the third stage ten minutes. There was no post-partum hæmorrhage. When asked the following day patient said that she felt much better after the drug, but remembered the whole of the labour vaguely until the mask was put on her face when she remembered no more. Patient "would like to have the drug with the next baby." Baby cried lustily when born and was healthy on discharge from hospital.

CASE 6. *Failure.*—One child previously. The drugs were given late in labour when the os uteri was four-fifths dilated. The total drugs given were nembutal grs. 3, chloral hydrate grs. 30, and chloroform with the birth of the head. The baby was born 1½ hours after taking the drug. There was no post-partum hæmorrhage. The drugs "quickened the pains and made them stronger." Patient was given chloroform with the birth of the head and she did not remember this part of the labour.

Conclusions.

(1) In our opinion this combination of drugs is safe and can be given to any woman in labour. (2) The drugs are easily portable and are given without trouble to the attendant or discomfort to the patient. (3) Judging by our experience the drugs may be administered by midwives but they must follow the technique carefully and never vary it without the direct permission of a medical practitioner. (4) In our series of 60 consecutive cases we have had 62 per cent. of painless labours without any ill-effects to mothers or children.

We would like to thank Mr. Eardley Holland for reading this paper and giving us the benefit of his criticism.

THE TREATMENT OF ANÆMIAS.*

By Janet M. Vaughan, D.M. Oxf.,
BEIT MEMORIAL FELLOW.

Our knowledge of the ætiology and therefore of the treatment of anæmia has advanced rapidly during the last few years. We know something to-day both of the factors which are necessary for normal blood production and of those which can interfere with or inhibit it. Treatment therefore should have a rational basis if, in any given case, we can determine what essential principle is lacking or what interfering factor is present.

Normal hæmatopoiesis is dependent upon adequate supplies of: (1) iron, (2) copper, (3) at least two substances present in whole liver, (4) vitamin C, (5) some complex of vitamin B, and (6) secretion of the thyroid gland. A lack relative or absolute of one or more of these factors will produce anæmia. The deficiency, whether single or multiple, may be caused by *faulty intake due to unbalanced diet*, faulty digestion in the gastro-intestinal tract, faulty absorption from the intestines, faulty distribution through pathological blood-vessels, or excessive strain placed on the normal storage depôts by (*a*) sudden or chronic loss, such as hæmorrhage, or (*b*) increased demand, as in pregnancy (Ivy et al.).

IRON.

Iron is an essential constituent of the hæmoglobin molecule. Lack of iron, therefore, however brought about, will cause an anæmia which can be relieved by the suitable administration of iron. These iron-deficiency anæmias, which would in the past have been classified as secondary anæmias, are characterised by a low colour-index—since it is the hæmoglobin-building factor which is lacking—and red cells which are normal or smaller than normal in size. They are :—

* Transfusion.

1. Idiopathic microcytic or hypochromic anæmia, a group which includes the Plummer-Vinson syndrome—i.e., dysphagia associated with anæmia and splenic enlargement.
2. Anæmia following acute and chronic hæmorrhage.
3. The simple or nutritional anæmia of infancy.

Idiopathic microcytic anæmia has been extensively studied in this country by Witts. It occurs largely in young middle-aged women, a study of the age-incidence showing a steady increase to a maximum between 40–47. The history is usually vague. Breathlessness, weakness, indefinite gastric discomfort, possibly sore tongue and dysphagia are the usual complaints. Clinically the spleen is palpable in about one-third of the cases. The finger-nails may show a spoon-shaped deformity. Achlorhydria is common but not invariable. The van den Bergh reaction is negative. Such cases respond as dramatically to large doses of iron as pernicious anæmia does to liver.

The underlying cause of the deficiency of iron is not clear, though some of the factors already noted as being of importance may play their part. In some cases there is deficient absorption from the gastro-intestinal canal. Mettier and Minot (1931) have shown that iron is more readily absorbed from an acid than from an alkaline medium; Minot and Heath have more recently found that the reticulocyte response to iron is of less magnitude in cases with achlorhydria than in those with free acid, which suggests that faulty absorption dependent upon lack of acid secretion is of importance. Since typical cases occur with a normal acidity, achlorhydria cannot be sole cause any more than it is in pernicious anæmia. Davies suggests that the excess of mucous secretion found in these patients may exert an inhibitory effect on absorption.

Faulty distribution probably plays a part in some cases. The *frequent occurrence of chronic* scurvy and pellagra in patients with arterio-sclerosis led Mettier and Minot (1931) to suggest that faulty absorption through such abnormal vessels was a factor in the production of deficiency diseases. Such defective absorption by the vessels must lead to faulty distribution to the tissues. Certainly arterio-sclerosis, if present, limits the efficacy of treatment with both iron and liver, since it is necessary to give bigger doses of the missing factor to obtain the same result in arterio-sclerotic subjects.

Faulty diet leading to chronic iron starvation is also of importance. Inquiry into the dietary history almost always procures the same answer: meat and green vegetables, the chief iron-producing foods, have either from personal taste, fear of indigestion, poverty, or laziness been taken sparsely for a long period. However, as patients with pernicious anæmia must always take liver, so patients with idopathic microcytic anæmia in the majority of cases must continue to take iron indefinitely, suggesting that there is some fundamental defect in iron metabolism present, apart from the contributory causes discussed. (Davies; Witts.)

* Transfusion.

The influence of an iron-poor diet on hæmoglobin production is apparent after gastric *hæmorrhage*. A small group of patients having severe secondary anæmia after gastric hæmorrhage were given not less than grs. 60 of Blaud's pill, in powdered form, daily. The average gain of hæmoglobin was 47 per cent. in an average period of 42 days (Table I.). Two of these cases, as indicated, also received one or more blood transfusions as an emergency measure nmediately after hæmorrhage, but without pparently influencing the result. In one there had een no improvement in a previous period of 64 ays in spite of transfusions and small doses of iron nd arsenic. A control series of patients who did not eceive adequate iron therapy had an average gain f 30 per cent. hæmoglobin in 79 days (Table II.). similar difference was apparent in the length of ime required for the red cells to reach a figure of 4,000,000 per c.mm. In the group receiving iron uch a level was reached in 23 days as compared ith 45 days in the control group (Table III.). It appears, therefore, that though the end-results were approximately the same in the two groups, a satisfactory blood picture was recovered more rapidly when large doses of iron were administered (Table IV.).

---

Average time in days ..	23	45

Presumably there is a deficiency of iron in the average diet given after gastric hæmorrhage and therefore delay in hæmoglobin regeneration.

Mackay has recently shown that the so-called *nutritional anæmia of infancy* is also due to deficient intake of iron and can be relieved by the administrations of iron alone. This form of anæmia is more common in artificially fed than in breast-fed infants presumably because there is less iron in cow's milk than in human milk. Infants are in part dependent upon the iron stored in the liver at birth, that taken in the milk is insufficient for growth and therefore, unless egg yolk, meat, and green vegetables are given it is important to add iron to the child's daily food. Apart from the effect on hæmoglobin production, she found that the morbidity-rate was halved in the group of infants who received iron as compared with the group who did not receive iron. She suggests, therefore, that grs. 1½ of iron ammonium citrate in chloroform water three times a day, reached by gradually increasing doses, or else a dried milk to which iron has been added, should be given as a prophylactic to artificially fed infants.

In all these iron-deficiency anæmias deficient intake of iron appears to play some part though especially in the idiopathic microcytic anæmia the body's power of absorption and distribution are also at fault. The essential in treating this group, apart from attention to general diet, is to maintain adequate iron intake. Blaud's pill administered in powdered form to ensure that the iron is readily available is the most satisfactory drug—ferrous salts being more readily utilised than the ferric salts (Witts). Ferric ammonium citrate is, however, also reliable; grs. 60 a day must be regarded as a minimum dose, while grs. 180 is well tolerated. Such large doses have been given to patients as soon as ten days after severe and repeated hæmorrhages with no complaint of discomfort and no return of bleeding. During the last few years, when these massive doses have been given, no evidence has been forthcoming to support the text-book dictum that iron produces constipation. Intravenous, intramuscular, and all proprietary preparations of iron are as useless as they are expensive.

COPPER.

The part played by copper in the treatment of hypochromic microcytic anæmias is still uncertain, but the possibility of its value should not be forgotten. A deficiency of copper will cause nutritional anæmia in the rat (Hart et al.). Mills claims that given in conjunction with iron it produces a more rapid response than iron alone. Young found that gr. ⅛ given daily in a pint of water relieved an anæmia that failed to respond to iron. Since only very small quantities are involved and many iron preparations contain such small amounts as an impurity it is difficult to assess the exact value of copper.

LIVER.

It is clear that liver contains two substances which effect hæmatopoiesis, since certain anæmias respond to the combination of whole liver and iron, which are uninfluenced by iron and liver extracts effective in pernicious anæmia. The anæmias responding to whole liver and iron are microcytic and have usually a low colour-index. They are anæmia associated with (1) chronic hæmorrhage (Murphy and Power), (2) starvation (Keefer and Yang), (3) deficient dietary in children (Batey), (4) past sepsis (Batey), and (5) carcinoma (Jackson and Minot).

Presumably in all these cases there is deficient intake of substances essential for normal blood production. The cachexia of new growth, for instance, is only too apt to become a vicious circle. The patient feels ill and therefore limits the diet, especially if the lesion is in the gastro-intestinal tract. Such limited diets do not contain the substances essential to blood production, and hæmatopoiesis is therefore inhibited leading to anæmia which results in further loss of appetite. Jackson and Minot believe that such cases are distinctly benefited by raw meat juice, especially liver juice, adequate iron, and vitamin-rich substances as butter and fruit. Davidson has found that iron alone will induce marked hæmoglobin regeneration in patients with malignant disease.

The anæmias which respond to liver extract, or its substitutes such as stomach preparations, can be grouped together as *megalocytic anæmias*. They have usually a high colour-index and there is an increase both in the size and the variability of the red blood-cells associated with a leucopœnia. Idiopathic or Addisonian pernicious anæmia, sprue, the pernicious anæmia of pregnancy, and pernicious anæmia associated with gastro-intestinal lesions fall into this group (Vaughan, 1931). Though differing perhaps in their clinical features the underlying disturbance of hæmatopoiesis is dependent upon a deficiency common to them all—i.e., in the gastric digestion of protein. Our knowledge of this primary defect in gastric digestion is due to Castle and his fellow workers. Their experiments show that gastric juice normally contains some substance essential for the proper digestion of protein leading to the production of a factor necessary for hæmatopoiesis. This failure of the gastric juice occurring in the pernicious anæmia syndrome is at present unexplained. There is clinical evidence that it may be complicated as in the case of iron deficiency by failure of absorption in the gastro-intestinal canal and of distribution through abnormal blood-vessels.

There are a few patients who do not respond to extremely large doses of potent material given by mouth, but who show a prompt response when quite small doses are given either intravenously or intramuscularly. Clearly there is some failure of absorption, since apparently refractile cases respond to small amounts of potent material if given by parenteral injection (Gänssten; Strauss et al.; Wilkinson). Intramuscular preparations are without danger. Intravenous preparations may produce a lowering of blood pressure, and should therefore only be used when the patient can be under constant supervision. The possible rôle of failure of distribution due to arterio-sclerosis is evidenced by the fact that a larger proportion of patients who require a high maintenance dose have abnormal vessels than those whose maintenance dose is low.

In treating the megalocytic anæmias the first essential is correct diagnosis, the second is a realisation of the importance of adequate dosage. An anæmia with a colour-index above 0·9 should at once be suspected of falling into this group. An increase in both the size and degree of variability of the red cells clinches the diagnosis. Achlorhydria is additional evidence, but since the essential deficiency is not of acid, the presence of acid must not negative the diagnosis of pernicious anæmia. Acid is often present in sprue. It may occur in the Addisonian or idiopathic form and in other megalocytic anæmias. The presence of cord signs and a positive indirect van den Bergh reaction may be of value but are not always present.

In treating such cases it is essential to keep the red cell count well above 4,000,000 (Beebe and Lewis). The majority of cases that are reported as having failed to respond to liver by mouth have never been given adequate dosage. The group already mentioned that are unable to absorb the effective principle are small. Patients with severe cord lesions invariably require a higher maintenance dose than those without such lesions, as shown by Beebe and Lewis. In a study of maintenance dose they found a number of cases which required the equivalent of three pounds of liver a day if the red cell count were not to fall below 4,000,000. They also isolated a small group of patients who, unless iron were given in addition to liver, failed to reach a maximum figure.

Thyroid deficiency may exert a varying effect upon hæmatopoiesis. In adolescents particularly, hypothyroidism is sometimes associated with a low colour-index anæmia which is relieved by thyroid administration. There are certain cases, however, in older people, which are often diagnosed as idiopathic pernicious anæmia, some of whom respond to thyroid treatment alone, while others require both thyroid and liver therapy for complete clinical and hæmatological recovery. The possibility therefore of a mild degree of myxœdema should not be overlooked in treating apparently refractile cases of either microcytic or megalocytic anæmia (Mackenzie; Means).

Hydrochloric acid in some cases relieves indigestion, especially if whole liver is being taken. There appear to be no contra-indications to its use.

The anæmia of scurvy has been shown by Mettier and co-workers (1930) to respond to vitamin C only. Liver and iron are useless. Wills has found that some factor associated with the vitamin B complex fed in the form of marmite is as effective as liver extracts in treating tropical megalocytic anæmia. Experimental work by Guha and Mapson also suggests that vitamin B is closely associated with hæmatopoiesis. How these substances exert their action is not clear, but their possible therapeutic value should not be forgotten in treating anæmias of obscure origin.

FACTORS INHIBITING HÆMATOPOIESIS.

The factors which exert an inhibitory effect upon hæmatopoiesis either directly or indirectly are: (*a*) sepsis; and (*b*) certain toxic substances as benzol, lead, and excessive exposure to radium and X rays.

In analysing the results of liver treatment it was found that less than 1 per cent. of cases of pernicious anæmia had died since the introduction of liver, and in all severe sepsis had been present (Vaughan, 1930). Further, cases with a mild degree of sepsis require larger doses of liver or its equivalent to reach a satisfactory red cell level than patients free of infection. A guarded prognosis should be given in febrile patients, while if a satisfactory response to adequate therapy is not achieved, possible sources of sepsis should be eradicated. *It is often necessary to increase the daily dose during intercurrent infections* as bronchitis or tonsillitis. Sepsis exerts the same inhibitory effect on the action of iron in microcytic anæmias (Minot). How this is brought about is not known. There is a close parallel in the effect on insulin.

In treating anæmias due to toxic influences as lead or X rays, it is first of all essential to remove the patient from all further exposure. If a severe aplastic anæmia is present transfusion may be necessary. Iron, whole liver, and a balanced diet should also be given.

Blood transfusion is our only remedy in a group of anæmias of whose cause we known nothing, and for which therefore we can offer no rational therapy, neither prevention nor cure—aplastic anæmia, erythroblastic anæmia, and anæmia associated with active sepsis, nephritis, and the Banti syndrome. Forkner and Scott maintain that large doses of arsenic invariably improve the red cell count in the anæmia of chronic myeloid leukæmia. The anæmia of acholuric jaundice is relieved by splenectomy.

It appears, therefore, that apart from the latter group anæmias must be regarded as deficiency diseases which vary both in their clinical and hæmatological manifestations according as to which of the factors essential for normal blood production are lacking. The deficiency may be brought about by faulty diet, faulty digestion, absorption, or distribution, or by increased demands. Our aim in treatment must be to supply the missing factors in such a way that they can be readily utilised. Success is largely dependent upon recognition of the extreme importance of adequate dosage.

THREE CASES OF ADDISON'S DISEASE

TREATED WITH AN EXTRACT OF SUPRARENAL CORTEX.

By H. W. Benham, M.B. Lond.,
Mary Fisher, B.Sc. Lond., M.R.C.S. Eng.,
I. More, M.B. Lond.,
and
C. J. L. Thurgar, M.B. Lond.,
HOUSE PHYSICIANS TO UNIVERSITY COLLEGE HOSPITAL.

In March, 1930, Swingle and Pfiffner[1] described the preparation of an aqueous adrenalin-free extract of the suprarenal cortex which revives comatose adrenalectomised cats and maintains them in perfect health; cessation of treatment with the extract is followed by death of the animals within ten days. Since then, 20 cases of Addison's disease treated with this extract have been reported in America by Rowntree and his co-workers,[2] and one case in England by Levy Simpson.[3] An immediate beneficial effect followed in 18 of these cases; in the other three the treatment failed, but in two of these adequate supplies of the cortical extract were not available at the time. In three of the successful cases the patient did not receive a further course of the extract when a relapse occurred, and died after returning home. The remaining 15 have continued to improve but have all required further injections of the extract from time to time.

Recently a cortical extract has been prepared in England on a commercial scale by a procedure resembling that of Swingle and Pfiffner. The efficacy of this extract in the treatment of experimental animals has been demonstrated by Wilson.[4] Four cases treated with it with favourable results have been reported briefly by Levy Simpson.[5] In the cases described below, treated with the same preparation, the beneficial effects were to a great extent offset by certain toxic manifestations.

Case Reports.

Case 1.—A woman, aged 45, admitted to University College Hospital under the Medical Unit on April 15th, 1931, complaining of indigestion for three years, weakness and vomiting for six weeks, and pigmentation of the skin for three weeks. Tuberculous arthritis of the right hip in childhood. She was very weak, but not wasted. Generalised patchy pigmentation maximal on the face and hands and in the axillæ; slight pigmentation of the buccal aspects of the cheeks. Blood pressure (syst.) 110–118 mm. Hg. No other abnormal physical signs discovered. Urine, no abnormal constituents. Blood count normal. X rays showed no disease in the lungs and no calcification in the suprarenal areas.

During the next week her condition became much worse: she could not sleep and vomited persistently, being unable to retain even small quantities of water. Acetone bodies appeared in the urine. Blood-sugar curve inconclusive owing to vomiting of some of the glucose used in the test; no glycosuria. Blood-urea 90 mg. per 100 c.cm. On April 22nd she appeared almost moribund, was extremely dehydrated and too weak to turn in bed; B.P. 102 mm. 6 c.cm. of the cortical extract and two pints of glucose saline were given by the intravenous route and continuous glucose saline per rectum. On the 23rd she was still weak and depressed. B.P. 104 mm. Two injections of 6 c.cm. each of the cortical extract given and one pint of intravenous glucose saline with 20 units of insulin to combat ketonæmia. On the 24th the temperature, hitherto normal, rose to 102° F.; pulse-rate 128. Urine contained blood, albumin, acetone, and sugar; normal amount passed. In spite of this the patient felt and looked better, taking by mouth more fluid than she vomited. B.P. 104 mm. At noon 6 c.cm. of the cortical extract was given intravenously. At 2 P.M.—temp. 104°; pulse 130. No symptoms except headache: no rigors. At 10 P.M. she had pain under the right costal margin. No abnormal physical signs found. On April 25th she passed flatus with relief of abdominal pain. At 11 A.M.—temp. 101°; pulse 132; B.P. 94 mm. Headache and discomfort in lower abdomen. Urine contained less blood, albumin, and acetone; no sugar. 6 c.cm. of the cortical extract was given subcutaneously with no subsequent rise of temperature. On the 26th the condition was very much improved. Vomited only 2 oz. in the night. Ate jelly and toast and asked if she might get up the next day. No further vomiting. Urine contained less blood, a trace of albumin, no acetone or sugar. Temp. now normal. 6 c.cm. of the cortical extract given subcutaneously, and repeated on the following day.

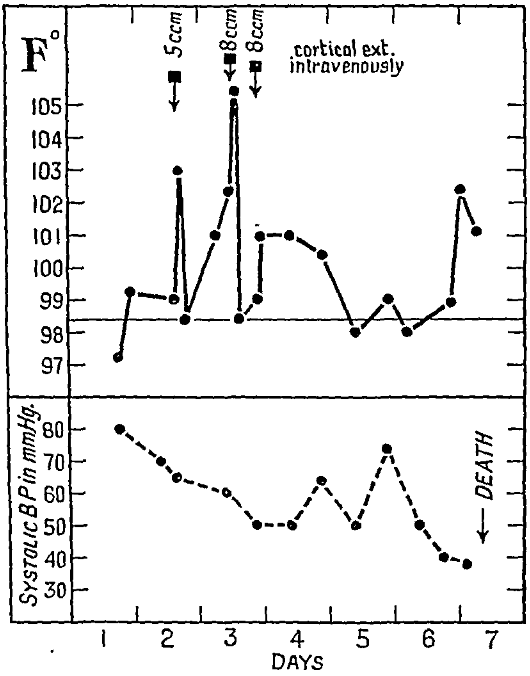
The administration of the extract was then stopped and improvement was maintained until April 30th, when intractable diarrhœa set in, following the administration of a mild purgative. Vomiting and weakness reappeared and blood, which had never totally disappeared from the urine, increased in amount. By May 4th she was again very weak and dehydrated; B.P. 78 mm. 6 c.cm. of cortical extract was given subcutaneously. At 6 P.M., another 6 c.cm. was given subcutaneously together with 1 pint of normal saline. Later she felt more comfortable and stopped vomiting. Early next morning, however, she suddenly became pulseless, with sighing respirations, and died in a few minutes.

Post mortem.—Heart: simple atrophy of myocardium. Lungs: normal; no evidence of tuberculosis. Liver: congested. Spleen: normal. Kidneys: rather congested, cortex soft and bulging; microscopically, a few fibrotic glomeruli seen, but no evidence of acute nephritis. Adrenals: twice the normal size and completely replaced by masses of firm yellow tuberculous caseation. Thyroid: normal. Pancreas: slightly atrophic; microscopically, the islets of Langerhans were normal in number; no hyaline or fibrous change. Right hip: healed scars of sinuses.

FIG. 2 (Case 3).



Temperature and blood pressure charts.

CASE 2.—A man, aged 24, first admitted under Sir Thomas Lewis on March 27th, 1931, with a history of loss of weight (20 lb.), and vague abdominal pains for two years, chronic cough for one year, and pigmentation, weakness, occasional diarrhœa, and vomiting for a few weeks. No previous illnesses. No history of tuberculosis in the family. He was somewhat apathetic and weak, and had a cough. There was moderate pigmentation of the face, hands, and of some acne scars on the back, but no buccal pigmentation. A few scattered rhonchi in the chest and slight tenderness in the left loin were the only other abnormal physical signs detected. B.P. 110/70 mm. Two sputum examinations revealed no tubercle bacilli. X rays showed slight infiltration of the apex of the left lung, but no calcification of the suprarenals. Blood count normal. Blood Wassermann negative.

As the patient's condition did not seem to require special treatment he was kept in bed and treated symptomatically. He improved rapidly and was discharged after five weeks to a convalescent home. Whilst in hospital the blood pressure readings were all above 110 mm. except for one of 96 mm. There was slight pyrexia, about 99, for the first few days; otherwise his temperature and pulse were within normal limits. On discharge his appetite was good but he had lost 4 lb. in weight.

He remained three weeks at the convalescent home, still feeling well. On returning home he rapidly became ill, with vomiting and weakness. After another week at home he was readmitted on June 16th, when his condition was found to be much worse and the pigmentation deeper. B.P. (syst.) 100–110 mm. After three weeks he was still very ill and it was decided to try treatment with the cortical extract; he was then extremely weak and apathetic, would take no solid food, and vomited once or twice a day; he slept badly and complained of abdominal pain. B.P. 76–84 mm. Blood-urea 84 mg. per 100 c.cm. Two intravenous injections of 6 c.cm. each of the cortical extract were given daily for a week, beginning on July 6th. By the third day of the course of injections he felt definitely better, his appetite began to return, vomiting had ceased, and he was sleeping well. By the end of the week he felt extremely well, had a huge appetite, was entirely free from pain, and wanted to get up. There was no appreciable rise of blood pressure and no change in the pigmentation. The injections produced no unpleasant reactions. During the week the temperature twice rose slightly (below 100°), but occasional slight pyrexia had occurred previous to the injections. Except for a trace of albumin on the sixth day the urine was normal. Blood-urea 32 mg. on discontinuing the injections. The improvement was maintained for ten weeks. He was up and about without fatigue and gained 1 st. in weight. The pigmentation was still unaltered, but the blood pressure rose during the six weeks following the course to a maximum of 108 mm. At the end of ten weeks the B.P. range was 96–100 mm., and he was then discharged feeling well.

On the same night a severe attack of asthma occurred which was relieved by adrenalin. During the next three weeks he was persistently asthmatic and vomited almost all his food. He was therefore readmitted on Oct. 20th, when the asthmatic attacks and vomiting promptly ceased. His appetite was good, but he was steadily losing weight. B.P. 90 mm. On Nov. 10th he started a week's course of four-hourly subcutaneous injections of adrenalin 1/1000. At the end of the week he felt stronger; he had gained 2½ lb. in weight, but there was no appreciable alteration in blood pressure. Improvement maintained until Nov. 25th, when vomiting returned and he had a typical attack of asthma, partially relieved by adrenalin. During that night and the next morning he had several attacks of asthma for which a total of 30 minims of adrenalin was given over a period of 13 hours; the last dose (10 minims) was given at midday. At 2.15 P.M. he felt better and drank a cup of milk. At 2.55 P.M. he died quite suddenly with no warning.

Post mortem.—Heart: small; some myocardial atrophy. Lungs: pleura adherent to chest wall; fibro-caseous masses at both apices; caseous patch in lower lobe of left lung; scanty recent miliary tubercles in upper lobes of both lungs; both lungs œdematous. Liver, kidneys, and spleen: normal. Adrenals: about one and a half times the normal size and almost completely replaced by tuberculous fibro-caseous masses; microscopically no normal adrenal tissue could be seen. Thymus: persistent, weight ½ oz.; microscopical structure typical. Pancreas: some fibrosis; islets normal.

CASE 3.—A woman, aged 43, admitted under Dr. H. Batty Shaw on Nov. 20th, 1931, with a four months' history of loss of appetite, loss of weight (21 lb.), occasional vomiting, increasing weakness, and gradual darkening of the skin. No previous history of illness. No family history of tuberculosis. Menopause at age of 35. She arrived in hospital very exhausted; temp. 97·2°; pulse soft, rate 72; B.P. 80 mm. Two days previously the B.P. was 92 mm. The whole integument was darkly pigmented, with patchy pigmentation inside the mouth. Some wasting, but not much dehydration present. Apart from the muffled character of the heart sounds physical examination revealed no abnormality in any of the systems; the urine was normal.

The next day she seemed the same, but the pulse was weaker and the B.P. 70/35 mm. Fluids were taken well by mouth. Urine excretion normal in amount. Radiograms of the chest and suprarenal areas were negative. By 3 P.M. the B.P. had fallen to 65 mm. (syst.); temp. 99°. At 3.15 P.M., 5 c.cm. of the cortical extract was injected intravenously. One hour later the patient felt cold and attacks of shivering began; temp. 103°, falling to 98·4° in two hours with cessation of shivering.

On Nov. 22nd the condition was unaltered. Temp. 102·4° at 10 A.M. B.P. 60/30 mm. At noon 8 c.cm. of the cortical extract was given intravenously. One hour afterwards attacks of shivering began; she became resentful of interference and almost unconscious at times. The temp. rose to 105·4°, falling sharply to normal within 1½ hours; the pulse-rate did not alter. That evening drowsiness and apathy continued, with occasional spasmodic twitchings of the limbs; no urine passed since 7 A.M.; pulse imperceptible; B.P. 50/30 mm. A third dose of the cortical extract (8 c.cm.) given intravenously, care being taken on this occasion to inject the warmed solution very slowly. Following this the temp. rose to 101°, but no other effects were observed. On the 23rd the patient could just be roused. Temp. 101°; radial pulse just palpable, heart-te 60/min., B.P. 50 mm. Blood-urea 118 mg./100 c.cm. lood-sugar curve normal. Taking fluids well by outh, no vomiting. Frequent spasmodic twitchings of e limbs present. Still passing no urine; only 240 c.cm. thdrawn by catheter at 1 P.M. (29 hours), containing a ght trace of albumin but no blood. Hot packs applied to e loins and diuretics administered. No more of the cortical tract given in view of the rigors. That evening she nproved slightly, the pulse was stronger, rate normal; P. (syst.) 64 mm.

On Nov. 24th, slight twitchings were still present. B.P. mm. Now passing small quantities of urine. Temp. ormal. Later that day there was a definite improvement; e twitchings entirely ceased, she was less drowsy, and oke sensibly to her relatives. Accompanying this change as a rise in blood pressure to 74 mm., an improvement in e pulse, and passage of urine in increased quantity. That ght continuous rectal saline administered, of which pints were retained. On the 25th B.P. fell to 50 mm. continent of urine and fæces: very weak. 6 P.M., patient uch worse; only just conscious at times, weakness treme. Pulse often quite imperceptible, heart-rate and unds unaltered. The temp. rose again to 102·4°; spirations rose to 44/min. and were sighing in character. P. 40 mm. (syst.) by palpation; no sounds audible over achial artery. No other abnormal physical signs found. drenalin and strychnine given with slight temporary provement. At midnight the pulse could just be felt; P. by palpation only 38 mm. Death occurred at 8 A.M. e next morning; no urine had been passed since 4 P.M. n the previous day, and none was present in the bladder st after death.

Post mortem.—Heart: small: some coronary atheroma. ungs: small healed scars at both apices; early patchy oncho-pneumonia. Liver: early nutmeg change; microopically fatty degeneration affecting the centre of the bules. Spleen: normal. Kidneys: rather pale: no ther abnormality either macroscopically or microscopically. drenals: pigmented and almost completely atrophied; icroscopically, a zone of normal medullary tissue surounded by a zone of vascular fibrous tissue containing ecrosed cortical cells, aggregations of lymphocytes, histioytes, and a few plasma cells. Thyroid: slightly atrophic. ancreas: normal.

Since the occurrence of these cases, our attention as been drawn to some untoward effects following ntravenous injection of the cortical extract in a ormal subject:

A. T. W., a subject in normal health, in an experiment n the action of the cortical extract on the basal metabolic ate in man, received a single dose of 10 c.cm. intravenously. Half an hour later malaise, headache, and muscular pains in he limbs occurred. One hour after the injection shivering ttacks commenced; the subject became collapsed, with lammy skin and feeble pulse of 100; B.P. 100 mm. One and half hours after the injection his condition had improved, ut shivering and pains particularly in the lumbar region were still present: temp. 103°; pulse soft, rate 107; respiraions 28; B.P. 130 mm. The next morning he felt better xcept for headache and universal tenderness of the skin; patchy erythema appeared all over the body and lasted 24 hours. Simultaneously herpes labialis appeared and lasted a little longer. Temp. 100·6°; B.P. 110 mm.; pulse 96. No other abnormal physical signs found. Two days later the temperature was normal and soon afterwards he returned to work. As a boy he was liable to have urticarial rashes.

Discussion.

The fatal termination of these cases of proved Addison's disease is disappointing when compared with the results of treatment obtained elsewhere, particularly as a beneficial effect followed administration of the cortical extract in Cases 1 and 2. The two factors militating against effective treatment were the disconcerting after-effects (seen in Cases 1 and 3) and lack of experience in the use of a new preparation. In Cases 1 and 2 definite improvement began after the third dose of cortical extract and was both subjective and objective. The patients rallied from their state of extreme asthenia, apathy, and depression, while vomiting ceased and appetite returned. In Case 1 the injections were combined with intravenous administration of glucose saline to combat dehydration; in Case 2 the extract was given alone. By the fifth day of the course of injections both patients wanted to get up and were eating and sleeping well. In Case 1 subcutaneous administration of the extract was substituted for intravenous after the rise of temperature and onset of hæmaturia following the third dose of extract. The relapse which occurred a few days later might, in our opinion, have been avoided had more of the extract been administered. The second case received a total of 78 c.cm. of the extract in 7 days. A few days later he was up and about the ward and began to put on weight. The average systolic blood pressure readings rose during the next six weeks by about 20 mm. of mercury. There was no appreciable alteration in the pigmentation. The improvement was maintained for ten weeks: vomiting then returned, together with attacks of asthma. On readmission to hospital, in view of the fact that vomiting had ceased, no further cortical extract was given, but the effect of a course of adrenalin was tried, which resulted in a gain in weight and strength. The occurrence of sudden death five weeks later indicates that the patient stood in need of the cortical hormone at the very beginning of the relapse. The temporary improvement following the course of adrenalin was comparable to that seen in cases treated by the Muirhead régime, which consists in administration of adrenalin to the limit of tolerance.

The severe rigors occurring in Case 3 within an hour of the injections appeared to accelerate the patient's downward progress; on the other hand, only 20 c.cm. of the extract were administered, an amount probably insufficient to produce the therapeutic effect. Suppression of urine occurred when the blood pressure was extremely low and a temporary rise of blood pressure was accompanied by passage of urine. In this connexion it may be noted that the critical level for urinary secretion is placed by physiologists between 40 mm. and 50 mm. of mercury; below 40 mm. cessation of urinary secretion invariably occurs (Starling). The infrequency of suppression of urine in Addison's disease may be accounted for by the rarity of very low levels of blood pressure. Smith[6] records a case which occurred at Guy's Hospital in 1897, before the days of the sphygmomanometer; Rowntree and Snell[7] refer to its occurrence a as terminal event. The occurrence of twitchings in Addison's disease is known but their cause is unexplained. The blood-urea in all three cases was raised; when the second case recovered from a crisis the blood-urea fell to 38 mg. per 100 c.cm. Rowntree and Snell[7] mention several cases with a raised blood-urea at a critical stage in the disease. A similar rise in blood-urea has been shown to occur with the onset of symptoms of adrenal insufficiency in adrenalectomised dogs (Rogoff and Stewart).[8]

THE TOXIC EFFECTS.

The toxic effects following the intravenous injection of the cortical extract consisted of rigors in Case 3 and in A. T. W.'s case, a high temperature and hæmaturia in Case 1, and slight albuminuria in Cases 1, 2, and 3. It is interesting to note that Cases 1 and 2 were due to tuberculosis, and Case 3 to atrophy, of the suprarenals. Similar effects do not appear to have been recorded by other workers, but in the first case of the recent series reported by Rowntree and his co-workers[2] there were some toxic symptoms which appeared one to two hours after intravenous injection of their cortical extract; these consisted of nervousness, nausea, and a feeling of coldness throughout the body. In this particular case no beneficial results following the administration of the cortical extract were observed, though a total of 500 c.cm. was given over a period of nine weeks.

In an attempt to elucidate the cause of these phenomena certain investigations of the commercial extract were carried out. Chemical tests by Dr. F. G. Young, at University College, London, failed to reveal the presence of adrenalin, though certain phenolic decomposition products of adrenalin were present; a minute amount of chlorbutol had been added as a preservative. A small trace of protein was definitely present, not amounting, however, to more than 10 mg. per 100 c.cm. of the solution. These results, with the exception of the finding of protein, agree almost identically with those obtained from tests conducted on their own extract by Swingle and Pfiffner. The samples of extract used in Case 3 and in the case of A. T. W. were tested for chance infection on account of the occurrence of the rigors and were found to be quite sterile. A. T. W. and one control were tested carefully for skin sensitivity to the batches of extract which had produced the rigors in his case and in Case 3. The results, which were negative, cannot be considered very conclusive since A. T. W. may have been in the negative phase of sensitivity following the intravenous injection; the difficulty of obtaining positive dermal reactions at any time is moreover well-recognised.

The tests, on the whole, suggest that the cause of the toxic effects was the trace of protein present in the extract. We are informed that a modification in the method of preparation of the extract is being investigated, which it is hoped will result in the elimination of all protein. If the preparation is given in its present form, great caution in regard to administration appears to be desirable; a preliminary dose of 0·5 to 1 c.cm. should suffice to demonstrate individual susceptibility; in the absence of any rise of temperature the ordinary doses of 5 to 10 c.cm. twice daily could then be given. The intravenous route has been found the best in the American cases, and was suitable in Case 2; subcutaneous injection was not followed by any local or general reaction in Case 1 though irritating local effects are mentioned by Rowntree and his co-workers; in animals the subcutaneous route is always used and found quite adequate. It would appear that as soon as the diagnosis of Addison's disease is made, the cortical extract should be given until the symptoms, with the exception of pigmentation, have disappeared. If there is a relapse a further course of injections should be started immediately symptoms reappear; delay until the patient is in a precarious condition renders treatment with extract more unsatisfactory.

Summary.

1. Three fatal cases of Addison's disease are described.

2. An aqueous, adrenalin-free extract of the suprarenal cortex was given intravenously in all three cases resulting in definite improvement in two which was not, however, sustained permanently after cessation of the treatment: the relapses did not receive prompt and adequate treatment with the cortical extract.

3. Certain toxic effects are described in two of the cases and also in a subject in normal health.

4. As a result of chemical investigations the trace of protein present in the extract is suggested as the probable cause of these untoward effects, which resembled on the whole those seen in protein shock.

5. Certain precautions are advised in regard to dosage and administration, if the preparation is given in its present form.

In conclusion, our thanks are due to the physicians of University College Hospital who kindly permitted us to publish details of their cases; to Dr. F. G. Young, of University College, for conducting tests on the extract; and to Dr. A. T. Wilson, of the Middlesex Hospital, for permission to describe his experiences.

THE BLOOD-SUGAR CURVE IN MENTAL CASES.

BY R. STRÖM-OLSEN, M.B., B.SC. WALES, D.P.M.,

JUNIOR ASSISTANT IN THE MEDICAL UNIT, WELSH NATIONAL SCHOOL OF MEDICINE, CARDIFF; LATE DEPUTY MEDICAL SUPERINTENDENT, BOROUGH MENTAL HOSPITAL, DERBY.

THE question of the abnormal blood-sugar curves often met with in certain types of mental patients has given rise to much discussion. One of the most recent comprehensive papers on the subject is that of McCowan and Quastel,[1] who clearly demonstrate the significance of the curve in manic-depressive insanity and define a hyperglycæmic index as a convenient measure for the degree of abnormality. The index is determined by the following formula:—

$$\frac{\text{2-hour blood-sugar level minus fasting level}}{\text{Highest blood-sugar level minus fasting level}} \times 100.$$

Before reviewing other published papers I will give the results of observations on 36 patients lately admitted to the Derby Mental Hospital. Originally 43 cases were examined, but since menstruation has been found to have a disturbing influence (McCowan and Quastel) the records of seven females menstruating at the time of the test have been omitted, all showing a hyperglycæmic index above normal. The mode of procedure in each case was as follows:—

A specimen of blood was taken in the early morning, the patient having fasted since the previous evening. Then 50 g. of glucose in 200 c.cm. of water was given by the mouth and the blood was examined at intervals of ½, 1, 2, and 3 hours. Folin and Wu's method of blood-sugar determination w[illegible] These results are recorded in the Ta[illegible], statement of the diagnosis, the bodily [illegible]al remarks.

Applying the hyperglycæmic index of McCowan and Quastel to the figures obtained in this investigation it will be seen on reference to the Table that an index over 50, which, according to these observers, should indicate a severe disturbance of carbohydrate metabolism, is given by 21 patients of whom nine had definite organic disease such as hyperthyroidism, diabetes mellitus, fatty degeneration of liver, cardi[illegible]vascular degeneration, or uræmia. *Of these patients, 14 were definitely undernourished, a few being even markedly emaciated; three of them had organic disease, and two were melancholics, whilst the remaining nine showed no evidence of somatic disorder.*

Apart from organic disease and emotional disturbance the state of nutrition of mental patients is of great importance in connexion with glucose tolerance. This is stressed because a large number of stuporose, confused, and depressed patients admitted to mental hospitals are found to be in a state of semi-starvation e to refusal of food or to obscure toxæmia. Bang[2] und that starving rabbits exhibited a greater and ore prolonged hyperglycæmia than well-nourished tes, and he concluded that in starvation the liver not prepared for glycogen formation. That this also the case in normal human beings is shown by angott,[3] who found a blood-sugar rise of 40 per cent. the fasting level in the normally nourished person ter the ingestion of 20 g. of glucose, whereas in the me person after three days' starvation an identical nount produced a rise of 243 per cent. The vestigations of Staub[4] made it clear that a reduced lycogen content of the liver caused maximal blood-gar figures after the administration of glucose, with rolonged hyperglycæmia, and he ascribes the efective glycogen formation to a transient hypofunction of the pancreas from starvation. Folin and Berglund,[5] on the other hand, from their work on glucose tolerance conclude that the glucose is disposed of by absorption by the tissues rather than by glycogen formation, and believe this to be the reason why prolonged hyperglycæmia does not occur in normal persons. The view that failure of or delayed glycogenesis in psychotics is associated with a disturbance of acid-base equilibrium has been brought forward by Mann and Scott.[6] Golla, Mann, and others[7] have recently found definite evidence that a large number of these patients show a disturbance of the $CO_2/NaHCO_3$ ratio of the blood, due probably to a failure of adjustment by the respiratory mechanism. The investigations of Eisner and Förster[8] revealed that hyperglycæmia after the

* Curve after administration of 100 g. glucose.

administration of carbohydrates does not necessarily depend on the difference in the rate of glucose absorption and glycogen formation. These workers found a rise of blood-sugar from 85 to 110 mg. per cent. during the ingestion of white bread, and after ten minutes the value was 153 mg. Their conclusion is that the presence of carbohydrates in the stomach has a specific dynamic action on the hepatic glycogen.

Although the series of cases herein recorded is not a large one it seems reasonable to assume that in the nine emaciated patients without organic disease or emotional disturbance the low state of nutrition was the only factor which might explain the high hyperglycæmic index. This abnormal physical state can no doubt cause: (*a*) transient hypofunction of the pancreas with deficiency or absence of hepatic glycogen (Bang, Traugott, and Staub); (*b*) defective absorption of glucose by the tissues of the body (Folin and Berglund); (*c*) alteration in the pH of the blood, due to starvation acidosis and possibly to failure of adjustment of the respiratory mechanism (Golla, Mann, et al.); (*d*) abnormal lability of the hepatic glycogen so that glycogenolysis readily occurs—e.g., from introduction of carbohydrates into the stomach.

Apart from defective nutrition and organic disease one must, of course, take into account adrenalinæmia and the emotional syndrome, when dealing with blood-sugar curves in mental cases. It is an established fact that adrenalinæmia is antagonistic to glycogen formation, as is shown by the following examples:

Blood-sugar Curve after Ingestion of 50 g. Glucose.

Patient No.	Fasting.	½ hour.	1 hour.	2 hours.	3 hours.
	mg. per cent.				
2	90	140	152	108	88
35	91	115	161	131	110
Curve after Administration of Adrenalin ♏ x Intramuscularly.					
2	98	182	159	103	90
35	90	188	170	141	88
Curve after Simultaneous Ingestion of 50 g. Glucose and Administration of Adrenalin ♏ x Intramuscularly.					
2	88	250	380	330	118
35	91	240	353	265	126

It will be seen that there is almost an arithmetical summation of the effects of adrenalin and glucose in these patients. A similar mechanism, though of less intensity, is at work in the production of abnormally high and prolonged hyperglycæmia following glucose ingestion during states of emotional tension.

SUMMARY.

The interpretation of glucose-tolerance tests in mental patients is one of great complexity and in each case several factors may require to be taken into consideration. From the results above recorded it appears that undernutrition per se plays a very important part in the production of a high hyperglycæmic index and due allowance must be made for this state. Furthermore, it is well recognised that the presence of certain organic diseases, especially endocrine affections (diabetes mellitus, hyperthyroidism, &c.), hepatic and renal insufficiency, and marked cardiovascular degeneration, have to be considered, as well as the physiological disturbance of menstruation and the emotional state at the time of the test.

I am indebted to Dr. J. Bain, medical superintendent of the Derby Mental Hospital, for permission to publish the results of these investigations and to Mr. V. P. Corke for valuable help in carrying out the biochemical tests.

VALUE OF THE
KLINE TEST FOR SYPHILIS.

BY T. E. OSMOND, M.B. CAMB.,
PATHOLOGIST TO THE VENEREAL DISEASES DEPARTMENT, ST. THOMAS'S HOSPITAL:
AND
K. E. HUGHES, M.R.C.S. ENG.,
ASSISTANT PATHOLOGIST TO THE DEPARTMENT.

IN order to estimate the value of the Kline microscopic slide precipitation test for syphilis we took 2000 sera and tested them in parallel with the Wassermann[1] and Kline[2] precipitation reactions; in addition, a certain number of these sera were also submitted to the Kahn[3] and Sigma[4] reactions. In this investigation only the "diagnostic" Kline test with *heated* serum was employed, except in the first 500 cases when the "very sensitive" antigen was also used.

TABLE I.—*Comparison of Kline and Wassermann Reactions.*

Complete agreement	1538	96·5 %	Disagreement	71 .. 3·5 %
Relative agreement	391		Total	2000

—	Relative agreement.			Disagreement.

Treated „	221	26	—	41	1	—
Not „	7	102	—	0	19*	—
—	241	128	22	46	20	5
	Total 391.			Total 71.		

* All negative W.R.'s and positive Klines.

A study of the Tables shows that the W.R. and Kline agree (more or less) in 96·5 per cent. of cases (1929), and disagree in 3·5 per cent. (71). In 46 of these 71 cases the Kline appeared to be the mor correct, and in 20 the W.R. (5 being undecided); whilst among the 391 relative agreements 241 favoured the Kline, against 128 in favour of the W.R. (the remainder being undecided). It will be readily seen therefore that the Kline test is decidedly more sensitive than the Wassermann; this was particularly evident in early and in treated cases of syphilis. On the other hand, the Kline test gave 1 per cent. of "false positives" against none with the W.R. Similarly the Kline proved rather more sensitive than the Kahn, but distinctly less specific, as evidenced three false positives in 480 cases; a comparison ith the Sigma test gave similar results.

The 2000 sera examined were taken at random ıd represented, for the most part, cases other than philis and cases of treated syphilis, together with a nall number of cases of early untreated syphilis. ı every case the diagnosis was very carefully estab-hed, so that an estimate of specificity as well as nsitivity could be made. In our hands the Kline st proved much more sensitive than the W.R., ıd rather more so than the Kahn or Sigma; in fact, appears to be the most sensitive of all the reactions ithin our experience, including the Meinicke, Müller, nd Hinton tests. It was more especially in early nd in treated cases of syphilis that the Kline showed s superiority. On the other hand, the incidence of false" positives (19 in 2000) was unduly high; re are quite unable to account for this, for the antigen mployed was that kindly provided by Dr. Kline imself.

ABLE II.—*Comparison of Kline and Kahn Reactions.*

omplete agreement .. 364 } 98·5% | Disagreement .. 7 .. 1·5%

isagreement ..	1	2	4	7
—	54	40	22	116

It appears, therefore, that the Kline test is of ıost value as an *eliminating* test for the exclusion f syphilis, and for test of cure rather than for iagnosis. Moreover, the test is so simply and quickly carried out (with practice 100 tests can be done in an hour) that it would be a practical proposition, where large numbers of sera have to be dealt with, to perform the Kline test on all and then retest all positives by the W.R. and/or one of the other flocculation tests.

On 500 sera the "very sensitive" Kline test was performed in addition, and it was found that this test was slightly more sensitive than the "diagnostic" and therefore preferable for eliminative purposes.

We have only a small experience of the Kline test on the cerebro-spinal fluid, but the fact that only fluids containing sugar (as proved by Benedict's test) are suitable for examination and the complicated and laborious nature of the reaction militate against it as a routine test.

CLINICAL AND LABORATORY NOTES

TETANUS FOLLOWING ULCERATION OF LEGS.

By E. C. Dutton, M.B. Manch., F.R.C.S. Edin.,
EDICAL SUPERINTENDENT, STEPPING HILL HOSPITAL, STOCKPORT;
AND
William More, M.B. Edin.,
ASSISTANT MEDICAL SUPERINTENDENT OF THE HOSPITAL.

A MAN, aged 61 years, of no occupation, was admitted to the Stepping Hill Hospital on August 1st, 1931, as a case of "ulcers of legs." He had extensive chronic ulceration of both legs, with parchment-like pigmented scarring surrounding the ulcers. The ulcers had been present for 12 years and were septic. He had dressed the ulcers himself with household rag and a proprietary antiseptic ointment. There had been difficulty in speaking and swallowing for four days before admission.

Examination showed tonic spasm of the jaws, but his mouth could be opened sufficiently for him to protrude his tongue. He could not swallow and articulation was difficult and indistinct. The pupils were round, regular, equal, and reacted to light and accommodation. The knee-jerks could not be elicited. The urine was normal. On August 2nd his condition was the same, except that the mouth could scarcely be opened. On the 3rd the neck muscles were rigid and there was some rigidity of the abdominal muscles. On the 4th there was definite opisthotonos, and in the early morning of the 5th he died. The case was apyrexial hroughout and he remained conscious until death.

The blood-urea was 47 mg. per 100 c.cm. The blood Wassermann was strongly positive 1/45 dilution.

Treatment was instituted on August 2nd by the administration of tetanus antitoxin intrathecally and intravenously in doses of 10,000 units under a general anæsthetic. Glucose salines were given per rectum and chloral and bromide added to the salines. Post-mortem examination on August 6th was negative except for fatty degeneration of the liver, possibly due to the long-continued septic condition of the legs. Pus from the surface of the ulcers on both legs was sent for pathological examination and the report was as follows:—

Bacteriological examination.—A stained film of the pus from the ulcer showed a few bacilli with round terminal spores, numerous streptococci and staphylococci. Tubes o cooked meat medium were inoculated with the pus and incubated anaerobically; in 48 hours the medium was turbid, with gas present, and some blackening of the meat had occurred; a film showed numerous round terminal-spored bacilli and streptococci. The culture was heated to 75° C. for 30 minutes to destroy non-sporing bacilli and a loopful inoculated into the condensation water of an agar slope as recommended by P. Fildes.[1] After 24 hours anaerobic incubation there was a fine growth over the whole surface of the slope and a feathery edge at the top. From this edge a subculture was made to another agar slope in order to be sure that the culture was pure, although a film showed only bacilli resembling *B. tetani*.

A suspension of the growth from the top of the second slope was made with saline, and 0·5 c.cm. was inoculated subcutaneously into the hind limb of a guinea-pig, a similar dose being given to a second animal which was protected one hour previously with 2000 units of tetanus antitoxin. In 18 hours the inoculated limb of the unprotected subject was extended, the muscles being in a tonic unrelaxing spasm; later in the day the other leg became involved but the spasm was not continuous. In 36 hours both legs were fully extended, the animal lay on its side, and when the cage door was opened a general spasm occurred, the head being drawn back; these general spasms became frequent and the animal died in 48 hours.

---

[1] Brit. Jour. Exper. Path., 1925, vi., 62.

Post mortem there was hæmorrhagic œdema at the site of inoculation extending up to the lower abdominal wall. Loopfuls of this fluid were inoculated into cooked meat and agar slopes and after 48 hours' incubation characteristic bacilli were seen in films from both the cultures. A culture of the blood was sterile.

The protected guinea-pig remained well for three weeks, when it was killed. Apart from some swelling of the limb where the culture was inoculated there was nothing abnormal post mortem.

Tetanus is a rare complication of chronic ulceration of the legs. In this case there was no traumatic history, nor evidence of wound contamination with soil. An identical case has been recorded by Dr. W. S. Brindle.[2]

We have to thank Dr. Lois Stent, of the Public Health Laboratory, Manchester, for the bacteriological investigation and report.

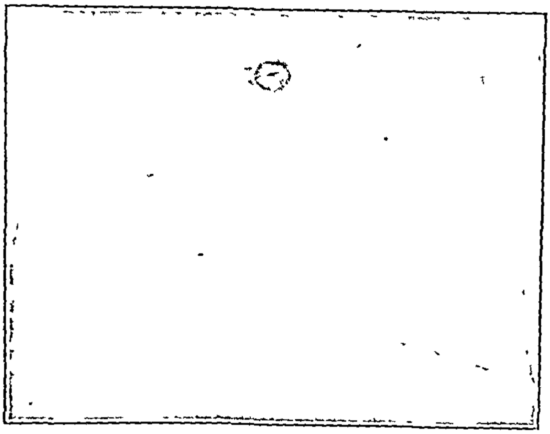
RUPTURED TUBAL GESTATION.

BRUISING IN THE UMBILICUS AND ON THE ABDOMINAL WALL.

BY W. E. TANNER, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE PRINCE OF WALES'S HOSPITAL, TOTTENHAM.

A WOMAN, aged 30, married five years but without children, was seen on Oct. 31st, 1931. She said she had had no previous illnesses and until the present illness the menstrual history was normal. The last period was on Sept. 24th. On Oct. 17th, as she was cooking the dinner, she suddenly felt severe pain in the vulva and a desire to pass water. The pain spread to the abdomen below the umbilicus and caused her to break into a sweat and feel faint. Soon she had an attack of severe vomiting. The pain and sickness continued; on Oct. 20th she noticed discoloration in the navel and on the following day this spread to the lower abdomen. She was seen by her doctor, who thought she had been kicked in the abdomen, and although she did not go to bed she was fairly comfortable. On the 30th she was again seized with severe pain in the vulva and abdomen accompanied by vomiting and faintness. She called in her doctor, who admitted her to a nursing home. The pains in the abdomen recurred at intervals of about 15 minutes. When seen on the 31st she said that her last period was one week late but she had had a thin pink discharge from the vagina on that morning.

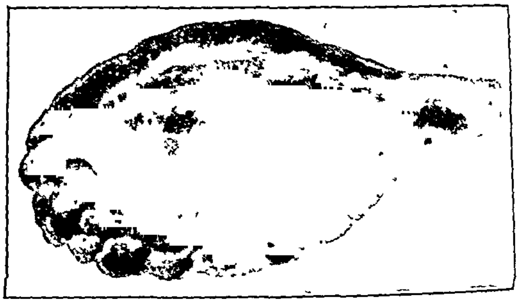
FIG. 1.



Showing "bruising" of the umbilicus and lower abdominal wall.

Examination.—She did not look anæmic. The pulse was 72 and the temperature normal. The abdomen was discoloured (Fig. 1). The bruising was just beneath the skin and the bright discoloration of the umbilicus showed that that was the part first affected. The lower abdomen was distended, slightly rigid, and tender, and there was movable dullness in both flanks. Nothing unusual was felt on rectal examination. A diagnosis of ruptured ectopic gestation was made and an operation advised.

FIG. 2.



The tube removed. (Natural size.)

Operation.—Median laparotomy below the umbilicus. There was no discoloration outside the peritoneum, but on opening the peritoneum the cavity was found to be full of blood. The right Fallopian tube was dilated at its outer end and surrounded by loose blood clot, but was lying free in the pelvis and not attached to any other structure. The outer part of the right tube was removed (Fig. 2) but the right ovary was left. The abdomen was closed without drainage. She made a good recovery.

The bruising was not the result of a retroperitoneal extravasation of blood from the pregnancy becoming attached to the parietal peritoneum. It must have come through the lymphatics at the umbilicus direct from the peritoneum into the skin and subcutis. I cannot find a record of any similar case.

A CASE OF ACUTE CHOLECYSTITIS.

BY J. H. PEEL, M.R.C.S. ENG.,
RESIDENT MEDICAL OFFICER, HILLINGDON COUNTY HOSPITAL, MIDDLESEX.

A WOMAN, aged 62, was admitted to Hillingdon County Hospital complaining of abdominal pain and vomiting. She was found to have a large ulcerating carcinoma of the left breast, and the history of the carcinoma dated back for five years. She had had two operations, and had recently been treated by deep X ray therapy, which had failed to check the advance of the carcinoma.

On examination of the abdomen, a lump the size of a lemon was felt in the right iliac fossa. It was tender, tense, and cystic; it was dull on percussion, and there appeared to be an area of resonance between the lump and the liver dullness. The lump was fixed. The rest of the abdomen moved on aspiration. The patient did not appear to be very ill, and was not in ny pain, except on palpation of the lump. The emperature was raised to 101° F. in the evening; he pulse-rate was 110, and the respirations 24. There was no history of jaundice nor of kidney rouble. The urine was normal, and the bowels quite egular. The patient had vomited twice on the day efore admission.

---

[2] Brit. Med. Jour., 1931, i., 396.

The diagnosis of secondaries in the peritoneum or he right ovary (breaking down) suggested itself, or possibly an appendix abscess. A laparotomy was performed, and the lump was found to be an enlarged and acutely inflamed gall-bladder. On palpating the neck of the gall-bladder a stone was felt in the position of the cystic duct. Cholecystectomy was performed. No stones were felt in the common bile-duct. On opening the gall-bladder after operation a single non-faceted cholesterol stone was found and the fluid distending the gall-bladder was faintly bile-stained mucus. There was no evidence of secondary deposits in the liver, peritoneum, or the uterine adnexa. The patient made an uneventful recovery from the operation.

SOME USES OF FARADISM IN TREATMENT AND DIAGNOSIS.

By H. W. Hales, M.D. Camb.

A woman, aged 42, sustained a motor accident which resulted in shock and pain in her back, sufficiently severe to keep her awake all night and produced by the slightest movement. A radiogram revealed a fracture of the right transverse process of the second lumbar vertebra. She always sat hunched up with her shoulders forward, supporting the weight of her body on the outstretched palms of her hands. There was a good deal of bruising over the left gluteal region, but no particular tenderness was noted here and radiography failed to reveal a fracture.

Diathermy and anodal galvanism to the lumbar region and coccyx did little to relieve her pain. I therefore tested the whole of the region between the first lumbar vertebra and the coccyx, extending four inches on either side, by the subfaradic test for cutaneous hyperæsthesia, according to the method of C. B. Heald.

In this test an indifferent electrode of moderate size is placed under the hand or at some point remote from the area to be tested; the other terminal is connected to a pointed electrode about one-sixteenth of an inch across. The current is so regulated that it is just imperceptible to sensation over a neighbouring area of normal skin. The electrode is then moved over the area to be tested. If the current becomes perceptible, the area where this occurs is charted and compared with the opposite side. Alternatively, a current which is just perceptible and quite painless over normal skin may be employed, and any definite increase in intensity or sign of pain noted as above. The alteration of the vibrating sensation of faradism to that of pricking or burning is a very definite sign and was originally described by Head in his classical paper. I have never found it present in a normal nerve.

The test showed a somewhat indefinite positive reaction for the spinal nerve immediately adjacent to the site of fracture. It was very positive, however, for the left posterior primary cutaneous branches of the first, second, and third sacral nerves. On testing this area, a particularly sensitive spot was found corresponding to the second sacral nerve. This spot was marked by a skin pencil. All four coils of the coil were put in the circuit, and the soft iron core withdrawn. The core was then suddenly inserted completely for a moment, with the pointed electrode over the marked spot. There was immediate relief, and apparently a complete cure of her symptoms in this region has resulted. As might be expected, the lumbar region of her back was still somewhat painful.

I have used the clinical application of this test for several years for the treatment of headache and allied conditions. A hypersensitive nerve, often the supra-orbital, is isolated with the usual small current, and then a strong current is applied for a moment. The results are often dramatic, and have usually been lasting. It has been employed in over forty cases, including neuralgia of several weeks' duration and severe influenzal headaches. The treatment is almost painless, and the percentage of successes is high.

Two theories suggest themselves as possible explanations of this phenomenon. The nerve sheath may be involved in minute external adhesions following hæmatoma or injury, and the sudden current may cause a contraction which breaks these. The nerve impulse is in the nature of an alternating current of 500 cycles, each of which consists of 10,000 high-frequency oscillations.[1] It is possible that the frequency in the painful nerve becomes slightly altered from that present elsewhere and thus causes pain. (Compare the hum present when an A.C. dynamo gets out of tune with the rest.) Possibly the faradic current overwhelms this non-synchronising current and then, when it has ceased, the normal condition of synchronisation is restored.

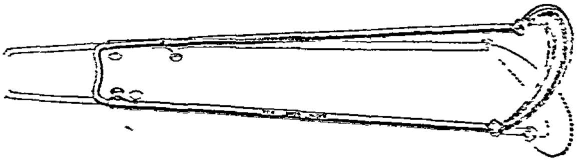
This method can be compared with galvano-acupuncture, and several patients have been relieved by the latter where the former has failed. I think that the method described is only effective for treatment where the nerve sheath is intact. The pain, which is relieved by galvano-acupuncture, is due to currents escaping from a nerve which is uninsulated owing to its destruction of its sheath as a result of injury.

The subfaradic test is of value in detecting cases of malingering. If the patient is prevented from seeing the test and the same spot is accurately localised on several different occasions, there can be little doubt that a pain is genuine. If, however, there is a wide divergence in the site of pain at each test, and there is reason to suspect malingering, doubt will be very much intensified by this method.

NEW INVENTIONS

A NEW HIP SPLINT.

This splint is intended for temporary use in motor accidents, and for moving patients by road. As will be seen from the illustration it is based in all particulars upon the principles of a Thomas hip splint and packs flat for use in an ambulance. It has a swivel joint on either bar below the buttock half circle. This allows for the splint being used for the right or left lower extremity as required. The anterior half circle being removed allows of application with ease and without pain.



Messrs. Down Bros., St. Thomas's-street, London, S.E., have made the splint from my design.

H. E. Rawlence, M.D., F.R.C.S.Edin.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE.

SECTION OF TROPICAL DISEASES AND PARASITOLOGY.

Dr. J. GORDON THOMSON, the President, took the chair at a meeting of this section on Jan. 7th, and Prof. W. SCHULEMANN, of Elberfeld, read a paper on

Synthetic Antimalarial Preparations.

He began by surveying the history of the use of quinine and of research into the nature of the malaria parasite and the rôle of the mosquito. Roehl's technique of experiments on canaries had made it possible to assess many groups of drugs in the laboratory, and the treatment of general paralytics with malaria, inoculated through the mosquito, provided a means of carrying out clinical tests of drugs on the human subject in northern climates. Quinine consisted of a quinoline ring bound to a basic heterocyclic group. An extensive search for other combinations effective in malaria had shown that the only ones with any definite action were methylene-blue and salvarsan. Investigators had prepared an extensive series of synthetic products with a constitution similar to that of quinine. It had been generally assumed that an antimalarial drug must contain a quinoline nucleus, with an aliphatic basic group bound by a carbon bond to the fourth position of quinoline. These researches had been unsuccessful. Prof. Schulemann and his colleagues had based their experiments on methylene-blue, substituting in one of its aromatic amino-groups an aliphatic basic group in place of an alkyl radical. Roehl had found this compound to be effective in bird malaria, but it had the definite characteristics of a dye. They had therefore transferred their experience to the quinoline group, uniting the basic aliphatic radical to the quinoline nucleus by a nitrogen bond. The first compound which they had prepared (amino-quinoline) had had a marked therapeutic action on proteosoma infection in canaries. Proceeding from this starting-point, and with full collaboration with physicians, the workers had produced a large variety of substances by changing the various components of amino-quinoline in different ways.

Roehl had tested all these compounds in animal experiments, and plasmoquine had been selected for practical clinical investigation. Prof. Schulemann demonstrated the formulæ of quinine and of plasmoquine side by side on the same chart. The gross formulæ and the molecular weights differed very little. Sioli, he said, had found plasmoquine therapeutically effective in malaria artificially inoculated for general paralysis, and Roehl had shown its action in natural human malaria; the latter worker had *also discovered that it destroyed the gametocytes* of *Plasmodium falciparum*, a property which quinine did not possess. This surprising result showed that plasmoquine was not a substitute for quinine, but had different therapeutic properties.

The three types of plasmodium, it was known, reacted to drugs in a different way, and it was also probable that the parasites reacted in different ways at various stages of their development. Work in British India had shown that with plasmoquine, alone or combined with quinine, it was possible to reduce the relapse rate of tertian malaria from 50 per cent. (the usual rate with quinine) to 2–5 per cent In subtertian malaria the results were not quite so satisfactory, but in this variety only was it possible to assess the value of plasmoquine at all accurately. Its action on the gametocytes of tertian malaria was not definitely known, and all that should be asserted was that it acted on the schizonts as well as on the gametocytes of *P. vivax*.

Quinine acted effectively on the schizonts of *P. falciparum* and allayed the acute clinical symptoms, but it could not inhibit the development of gametocytes and even appeared to stimulate it. Plasmoquine, while it had practically no effect on the schizonts, destroyed the gametocytes in a few days, but it did not inhibit their formation. Minimal doses which were too small to destroy the gametocytes nevertheless prevented them from infecting the anopheles. Here, for the first time, it appeared possible to break the cycle man-mosquito-man, and work along these lines was being performed in West Africa, but plasmoquine had in no way superseded the usual sanitation methods.

Prof. Schulemann exhibited a diagram representing the development of the malaria parasite. In subtertian malaria, he said, quinine broke the cycle at the stage of schizogony, while plasmoquine broke it at the stage of gametocyte formation. However, it was not known which phase gave rise to relapses and what drug affected that phase; nor was it known what drug affected the development of the sporozoite into a ring form. Warrington Yorke and Macfie had shown that quinine had no causal prophylactic action in malaria, but James had shown that plasmoquine had that action. This work was the starting-point of important future research. It ought to be possible to discover new drugs which might attack the cycle at other points. The lecturer mentioned recent work along these lines.

Mietzsch and Mauss at Elberfeld had formulated another heterocyclic ring system and the resulting compounds had been tested by Kikuth. The new product differed in its action from plasmoquine and would probably be effective against the schizonts though not against the gametocytes. It seemed to have advantages in dosage and duration of treatment, and to reduce the number of relapses. It was known provisionally as "erion," but this name was not to be used in future.

Prof. Schulemann concluded by emphasising the importance of collaboration with other investigators, and paid a tribute to the help he had received from workers in the British Empire.

DISCUSSION.

Sir HENRY DALE pointed out that work of this kind did not follow logical sequence, although the subsequent account of it might be logically expressed; its success was largely due to careful and patient research on the lines of trial and error.

Lieut.-Colonel S. P. JAMES remarked that the observation of the action of plasmoquine on the parasite in its different stages had led to important changes in current ideas and aims in the chemotherapy of malaria. Whereas, formerly, it had been generally believed that the problem was the single one of finding a drug which would act more effectively than quinine *in malarial* attacks, the problem was now realised to be fourfold. Plasmoquine was the r drug known at present to destroy the sporozoites, even it would not give complete protection under cting conditions. Quinine was effective against asexual parasites. On the sexual forms plasmone acted excellently. in smaller doses than against sporozoites. The speaker doubted whether smoquine really reduced the relapse rate; in lignant tertian malaria it was no more effective this respect than quinine. This had been shown five cases at Horton. One of the difficulties in praising a drug was the existence, in each species parasite, of various strains, differing in virulence. inine had proved effective against *P. falciparum* ection from India and West Africa. but not against ains from Rome and Sardinia. It was important know whether the good results obtained with the w drug could have been obtained with quinine. r the chemoprophylaxis of malaria a drug was eded with the same action as plasmoquine, but s toxicity; for chemotherapy one was needed ich, given in moderate doses for a short period, uld not only cure the attack. but prevent relapses.

Prof. WARRINGTON YORKE wondered whether it s really true that *inoculated sporozoites immediately* tered the red corpuscle. He thought it possible at in ordinary malignant tertian malaria the rings ltiplied in the red cell. Before plasmoquine had en introduced, gametocytic crescents had been own to disappear from the blood under a heavy se of quinine, and possibly they did not live very ng in any case. If any real advance in chemoerapy were to be made, the biological side must not burked. Quinine was a unique and remarkable ug. and it was not creditable that so little was ow about its action.

Prof. ROBINSON described his investigations of bstances of the plasmoquine type. He was, he id. experimenting on derivatives with a short carbon ain, with one alkyl group at the end. Whenever departed from Prof. Schulemann's work, the tivity seemed to disappear.

Sir MALCOLM WATSON said that the gamete did t come off where Prof. Schulemann had shown it. e would himself have more faith in a drug that stroyed the schizont than in one which only acted pon the gamete. He hoped to try plasmoquine n the population of a large copper mine near the ongo border. where accurate observation was possible. alaria in a cold climate was not always the same ing as in the tropics.

Dr. P. H. MANSON-BAHR stated that patients ith benign tertian malaria had been particularly rateful for plasmoquine. Clinically and expenentally, plasmoquine was specific for *P. vivax;* had less action on the quartan and still less on the erozoites of the subtertian forms. Its most emarkable action was upon the gametocytes. specially in combination with quinine. It had no itter taste, and did not readily provoke toxic mptoms in children; it was especially useful for regnant women, for it was harmless and tended to revent relapse; and it was valuable in the onvalescent stages of blackwater. Possibly plasmouine acted as a chemical alterative of quinine, nhancing its value. An idiosyncrasy undoubtedly xisted, and plasmoquine cyanosis appeared, especially n recent victims of malaria who had basophilic egeneration of the blood corpuscles, but it was not very dangerous condition. It was undesirable that patients should dose themselves, but this possibility fforded no reason for condemning the drug out of hand. The prejudice against it in West Africa probably existed because over 90 per cent. of the malaria in that country was subtertian.

Dr. M. A. ARAFA described the results of plasmoquine treatment on over 100 patients in Cairo. Combined with quinine it caused no toxic symptoms and cured the *intestinal and hepatic disorders* associated with malaria. The results of the intravenous injection of plasmoquine compound were not better than those of oral administration, and the blood pressure tended to fall. The most convenient dose was 0·04 g. plasmoquine and 1·2 g. quinine daily for one week, followed by four days' rest and three days' treatment alternately for the next five weeks. This combined interrupted treatment sufficed to clear the blood of both rings and crescents in an average of four days and without toxic symptoms. Only three relapses had occurred.

REPLY.

Prof. SCHULEMANN, in reply, emphasised the necessity for distinguishing carefully between tertian and subtertian malaria. In the subtertian form plasmoquine ensured that the gametocytes should be rendered ineffective in a day or two. It was necessary to exercise great caution in administering new preparations, because substances with short side-chains had been known to cause disorders of the central nervous system which were not apparent in experimental animals. It was neither necessary nor desirable to give pure plasmoquine intravenously, for it was not effective in coma, the only condition in which intravenous injection was requisite, and it acted upon the bundle of His to cause heart-block.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

AT a meeting of this association, held at University College. London, on Jan. 8th, with Dr. G. E. FRIEND, the President, in the chair, a discussion took place on

Physical Education in Schools.

Mr. T. N. MORTIMER BOOTH (physical instructor, Christ's Hospital) said that the admitted lack of any uniform system in schools might be largely due to the difference in the type of personnel responsible for the methods adopted, and to the lack of the complete training of the teacher The relation of the physical to the mental development of the boy should always be kept in mind; then a due relation would be observed to the other subjects in the curriculum. It was not now believed that the ordinary games of school life sufficed for every type of boy, there should be close inspection and control by the competent physiologist. No system could well be applied to all types of school, and the numbers of pupils to be dealt with entered into the question very importantly. Also there still existed the old conflict between the methods evolved by the Army school and by the Board of Education. It was wrong. in the speaker's view. to regard the Army instructor as too limited in outlook. to consider that his exercises were fit for adults only, and that his drill did not make for mental alertness. So-called "drill" Mr. Booth did not consider soul-destroying if it was done in the right way. It should not be thought enough to lump all boys together because they were of the same age, for all sorts of problems were presented by the individual. In the experience of all instructors, there were boys who hibernated during school hours and only emerged from their torpor as meal-time approached. None but the fully trained could be regarded as suitable for school instruction, and of these the supply must necessarily be limited. It was recently declared that it required three years to turn out a fully competent woman instructor; also that the physical education of our sons was half a century behind that of our daughters. The director of physical education should see each boy with his form daily, but the difficulties in the way were immense. In a large school there might be 20 or more forms, and the later hours of the day were not suitable for the purpose. Perhaps more time would be assigned by headmasters for physical education when a boy was allotted so many marks in his school certificate for his chest expansion. How should the results of physical education be tested, and by whom should the testing be done? On one hand it was suggested that the physical training expert should have the matter largely in his own hands, and that he should even be expected to advise the headmaster on questions of food and clothing, the medical officer being very much in the background in this respect, as he was associated in the mind of the boy with the stethoscope and disease. The practical experience at Christ's Hospital, however, went to prove the reverse of this—namely, that the medical officer should be in the foreground and be associated with physical fitness. The study of biology should greatly facilitate a greater interest being taken by the boy in the function and condition of his own body. At Christ's Hospital Dr. Friend saw every boy, apart from cases of sickness, three times every term for purposes of measurement; and the records constituted valuable data, which were subsequently available for both the medical officer and the instructor. Apart from the preparatory school, there were 700 boys, aged from 10 upwards, and besides leading a full and active life out of school at the games in season, they took part in such domestic routine as cleaning their shoes, making their own beds, and serving at table, so that little time was available for organised physical training in out-of-school periods. In this school a compromise in the way of exercise in proper costume between 10.30 and 11.5 A.M. each morning had worked happily for years, and resulted in the second part of the morning's studies being attacked with enhanced zest.

DISCUSSION.

The PRESIDENT showed a series of graphs illustrating seasonal variations in weight and measurement of the boys at Christ's Hospital, and including the results of the war rationing.

Dr. MURRAY LEVICK said that the London University advisory committee on this subject (of which he was a member) had fully considered the fact that physical fitness of school boys and girls depended not on exercises alone, but on the four factors: exercises, diet, atmospheric hygiene, and a properly arranged time-table. Juvenile health had reference to many subjects with which the schoolmaster could not be expected to be expertly conversant, therefore the hygiene of a school should be supervised by a specialist. At many schools the meals served were sadly lacking in vitamins. The breakfast at one large public school, for instance, consisted of white bread and butter, tea, kippers, marmalade, or jam. At another the only meal between midday and breakfast the next morning consisted of white bread and butter and one of the three following: potted meat, cake, sardines. The director of physical education in a school should be able to coöperate with the medical officer in the supervision of the school dietary and the ventilation of the school rooms and dormitories. Girls' schools were far ahead of boys' schools in the matter of physical education; and he advocated starting a three months' course in physical education for masters in charge of games at boys' schools. He also thought general practitioners, fulfilling the post of medical officer at a school, should pay regular visits to the school and supervise the choice and serving of the foods.

Major GARNIER (superintendent of the Lucas Tooth Physical Training Institute, Bermondsey) described his methods. He found it essential, he said, to have an attractive programme, otherwise the youth it was his special aim to secure would not continue to attend. His view was that three years' training was needed to make an efficient whole-time instructor. His pupils ranged in age from 14 to 44, and he had now 250.

Mr. F. CAHILL pleaded for an immediate practical outcome of this meeting. He was disappointed with the way in which the Board of Education had attempted to deal with this question.

Mr. R. E. ROPER exhibited some graphs with the object of showing that there might be a causal relation between a low or inadequate dietary and the onset of a definite cerebral disturbance. One showed that a period of concentracted cramming for examinations coincided with reduced measurements and poor appetite. In another, a boy committed thefts and other misdemeanours when his weight was at its lowest.

Dr. G. P. CROWDEN considered that the first care of the school doctor should be devoted to diet; it must not be assumed that the nutrition of the school boy would look after itself. Training should be placed next. The efficiency of the school medical officer was not to be judged by the extent of his practice; his work in the school life was preventive. Unless he knew what was necessary in this way he would not be able to control the conditions which would lead to the maintenance of the boy's health and proper fitness. He agreed with Mr. Booth's suggestion that marks should be given in the boy's certificate for physique, as that would greatly encourage him to take an interest in his physical condition. Three bodies which had greatly interested themselves in this question were the British College of Physical Training, the Gymnastic Teachers' Institute, and the National Society of Physical Education. These had now amalgamated to form the British Association for Physical Training. He preferred the term "physical education," for that implied a study of school hygiene, physiology, and anatomy. Over a thousand school teachers had taken the association's certificates. Leeds had taken the first organised step to provide training for those who wished to become physical instructors, for both elementary and public schools, and he hoped that the London County Council, or London University, would see its way to take up this subject and raise it to University status.

Dr. L. R. LEMPRIÉRE said he had been medical officer of Haileybury College for 22 years, and had control of the physical training at it. It had been of great advantage to him, for it enabled him to know the boys, and to study them when they were on the move, in a way that would not have been possible otherwise. Two types of physical training were at present carried ut in schools. One was the free-standing exercise' one by the entire school probably once a day, and ntrolled largely by the senior boys, who had been ught their part. The other kind consisted of ee-standing work plus apparatus work, carried ut by only part of the school and for a short time, nd supervised and directed by trained instructors. n a general way, ground work alone was not sufficient; nd he questioned whether the senior boy could be apable of instructing adequately. The boys who ost needed physical training were those of subormal physique under 16 years of age. Certainly he best results he had seen came from a combination f the two systems. A good stance, alertness, and apid response to command he regarded as very mportant.

Mr. BROCHS spoke from a particular experience of econdary schools, and highly recommended a book n the subject which had been issued by the Board of Education. Just before and during examination ime there was a strong tendency to allow exercises o be neglected, yet that was the time when they were most beneficial.

The PRESIDENT said the control of physical training n schools could not be the sole matter of the medical fficer, nor even of the director of physical education in the school; it depended on a correlation of the interests and the activities of the whole of the school life.

PATHOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

A MEETING was held at Guy's Hospital on Jan. 8th and 9th, Prof. R. DONALDSON being in the chair.

R. A. Q. O'MEARA (Dublin) discussed the biochemical mechanism of the formation of acetylmethylcarbinol, which is of interest to bacteriologists because it is the basis of the Voges-Proskauer reaction. —S. J. HARTFALL and L. J. WITTS (London) described their extensive observations on persons with achlorhydria who may have normal blood or may suffer from secondary microcytic or macrocytic Addisonian anæmia. Their gastric juice obtained with histamine will act on minced beef with the production of Castle's factor which is effective in curing pernicious anæmia.—C. J. POLSON (Leeds) described three cranial tumours which produced the chiasmal syndrome by involving the optic tracts: a pinealoma, a carcinoma of the ethmoid, and a tumour of Rathke's pouch.—J. DAVIDSON (Edinburgh) in a long series of cases of fatal eclampsia found the liver necrosis variously situated in the periphery or centre of the lobules. The kidneys relatively rarely showed tubular degeneration and hæmorrhagic lesions were uncommon in both organs.—J. W. ORR (London) described the reaction of the lymphocytes and histiocytes of the rat's spleen to infection with streptococci.—A. E. BOYCOTT and C. L. OAKLEY (London) gave an account of the extensive pleural effusions which are the cause of death in rats living in air containing 95 per cent. of oxygen, and of their failure to make rats anæmic by keeping them for many weeks in 50–60 per cent. oxygen.—J. H. DIBLE (Liverpool) by chemical analysis found a good deal more fat in the parts of human hearts showing histological fatty degeneration than in the neighbouring normal muscle.—G. R. CAMERON (London) described how earthworms react to foreign bodies by phagocytosis by the cœlomic cells, by expulsion through the dorsal pores, by extrusion through the nephridia, and by getting rid of the affected parts altogether by autotomy.—C. E. JENKINS (Salford) had deduced a formula for calculating the volume of a red corpuscle which he made to be about 82 cubic micromillimeters. He also described an ingenious method for ascertaining the relative volume of red cells in blood by measuring the relative volume of plasma by adding laked blood. The method gave results about 10 per cent. lower than those given by the hæmatocrit.—W. M. CROFTON (Dublin) showed lantern slides of microbes which he had isolated from sarcomata and claimed to have produced sarcomata in rats with them; J. A. MURRAY had seen the lesions and thought they were abscesses.—HELEN CHAMBERS and GLADWYS M. SCOTT (London) showed that emulsions of rat sarcoma developed some substance after standing a short time which on inoculation into rats rendered them refractory to tumour implantation. No protective effect had been obtained with any preparation which was certainly free from cells, though it was not clear that cells as such were responsible.

T. LUMSDEN (London) continuing his observations with the euglobulin fraction of an anti-human-cancer sheep serum containing the anti-malignant bodies, found that the serum caused necrosis of spontaneous mouse tumours when it was injected into them, and that this so immunised the animals that autoplastic transplantations made a few days later nearly always failed.—C. H. ANDREWES (London) showed that several different fowl sarcomata could be transplanted successfully into pheasants though they could not be carried on in these birds.—S. P. BEDSON (London) gave a number of reasons for thinking that the elementary bodies in psittacosis were indeed the causative virus of the disease, and J. C. G. LEDINGHAM (London) gave a convincing demonstration that during an attack of vaccinia a rabbit develops agglutinins for the corresponding vaccinial bodies which increase and decline in the same sort of curve as is familiar in the antibody reaction to bacteria.—W. J. ELFORD and C. H. ANDREWES (London) showed that each sort of bacteriophage had a characteristic size varying in different kinds from about 8 to about ·75 micromillimetres.—R. W. FAIRBROTHER (Manchester) had found that mixtures of vaccinia virus and antiserum which were neutral by the skin test would kill rabbits on intracerebral inoculation.—A. T. GLENNY and MOLLY BARR (London) showed, in a series of elegant experiments, that mixtures of diphtheria toxin with some preparations of antitoxin might dissociate so much after inoculation as to kill the test animal whose blood might contain enough free toxin to kill a second animal in quite small doses. They pointed out the consequent danger of toxin-antitoxin mixtures prepared for immunisation and said that it was difficult to devise a perfectly satisfactory animal test of their safety for human use; P. HARTLEY agreed with this, and urged that for this purpose toxin should always be replaced by toxoid.—A. FELIX (London) discussed the factors which determine the type of antibacterial antibodies found in normal animals.—H. J. PARISH (London) pointed out that cultures of the meningococcus and other delicate bacteria could be satisfactorily preserved alive for a long time by covering them with liquid paraffin.—J. G. THOMSON (London) gave an interesting account of the occurrence of the protozoon *Glugea anomala* in sticklebacks near London.—MARY M. STEWART (Aberdeen) described the bacterial flora of the skin and alimentary canal of the haddock.

(*Continued at foot of next page.*)

REVIEWS AND NOTICES OF BOOKS

Radiologische Praktika.

Band XVIII. *Einfuhrung in Die Röntgen-Therapie Erkrankungen.* By Priv.-Doz. Dr. J. PALUGYAY. Leipzig: Georg Thieme. 1931. Pp. 103. M.10.

THIS is in many respects a valuable monograph on the X ray treatment of surgical diseases: it is a short survey of the present position in the application of X rays to the various conditions covered by the title, and is intended to serve as an introduction to the study of more elaborate treatises, to the position of which it makes no pretence. General biological and technical details are omitted, but fairly close accounts of the techniques used by the author or to be found in medical literature are given. Throughout, the doses are stated in international *r*, and it is pleasant to see that the author has freed himself sufficiently from the shackles of the unit skin dose, not only to employ the *r*, but also to give the doses which should be received at the lesion below the surface, and not merely the dose on the surface.

The two sections of the book which will probably be of greatest general interest are those devoted to the treatment of surgical tuberculosis and malignant disease respectively. With respect to the former, the author advocates homogeneous irradiation, for instance, of the joint, with very small doses of penetrating radiation, even though the lesion might be thought to be accessible to larger doses of softer rays. It is maintained that it is "better to give much too little than a little too much" in the treatment of tuberculous lesions, doses of the order of 25–50 r. being recommended per sitting. It is perhaps unfortunate that no statistics regarding the results of these techniques are given. The problems of the X ray treatment of malignant disease are very cautiously treated, it being maintained that in many cases, almost most cases, the treatment is only palliative. The general considerations here given form a clear account of the fundamental difficulties, and it is insisted that the problems are not merely those of X ray technique, but call for careful regard of the patient as a whole. Where the techniques are given, there are suggestions for dosage in the treatment of malignant disease in various parts of the body.

The book is, unfortunately, not illustrated, and a few diagrams have replaced suitably some of the text. It is very well printed and produced, though proper names in the text seem sometimes unduly Germanised. A bibliography is included, and appears a reasonable selection from the mass of material available.

(Continued from previous page.)

Demonstrations included the following:—R. J. V. PULVERTAFT (London): (1) A gumma of the thyroid gland in a girl of 18. (2) Leiomyoma of the renal pelvis. C. POLSON (Leeds): (1) Complete (post-traumatic) stenosis of the larynx. (2) Hæmochromatosis and primary cancer of the liver. H. ROGERS (Bristol): Bilateral suprarenal tuberculosis with a tuberculoma of the basal ganglia of the brain. H. E. HARDING (Sheffield): (1) A large cyst of the spleen containing mucoid material and lined by squamous epithelium. (2) An unusual mass in an epididymis: ? granulomatous, ? neoplastic. H. H. GLEAVE (Liverpool): Periarteritis nodosa. ELIZABETH H. LEPPER (London): The use of tellurite-containing medium for the isolation of streptococci. T. HARE (London): Foot-and-mouth disease lesions in the ear epidermis of inoculated guinea-pigs. F. A. KNOTT (London): (1) Specimen and sections of Gaucher's splenomegaly (splenectomy). (2) Specimen and sections of active ulcerative colitis (colectomy). JOAN M. ROSS (London): (1) Chorion-epithelioma secondary to a testicular tumour. (2) A further case of splenomegaly of unusual type. (3) Primary carcinoma of the Fallopian tube. C. OLDFIELD and M. J. STEWART (Leeds): (1) Endometriosis carcinomatosa. (2) Liposarcoma of broad ligament. ELLA M. HICKMAN (Leeds): Neurofibromatous epulis.

The Chest in Children Roentgenologically Considered.

By E. GORDON STOLOFF, M.D. Foreword by BELA SCHICK, M.D. Annals of Roentgenology. Vol. XII. New York: P. B. Hoeber. Pp. 432. $15.

THIS study is largely a clinical one, by an author who is displayed as an expert radiologist as well as a sound clinician. This combination of specialties is rare in England where it is considered to be an advantage for the patient to have the opinions of two medical men who look at his case from different angles. Much labour has evidently been devoted to this work and many of the observations extend over a long period of time. The serial radiograms are of great value in the study of the evolution of certain pathological processes, particularly tubercle and the pneumonias. It is especially difficult to get good radiograms of the chest in children. In view of the excellent quality of these it is disappointing that little is said about technique. It would be interesting to know the focus-film distance used, whether 6 ft. or the more American fashion of 4 ft. Another omission is the lack of reference to appearances found in radiograms of the normal chest in children of various ages.

A detailed description of the topography of the interlobar fissures is given, many radiograms, anterior and lateral, illustrating interlobar effusions, and others showing the variations of technique which enable pathological changes in the large interlobar fissure to be interpreted. The importance of the lordotic position is well seen. It is not quite clear whether the author believes it possible to visualise these fissures in normal radiograms, the lesser in postero-anterior, and the greater in lateral views. In Fig. 177, the author refers to a *hair-line pleural thickening* of the small interlobar fissure; as a matter of fact a similar hair-line is seen in other radiograms throughout the book, particularly in Fig. 75. It is likely that these fissures can be visualised in 80 to 90 per-cent. of radiograms of the healthy chest. A large and important section of the book, with many serial radiograms, illustrates the evolution of the primary tuberculous complex in children—that is the primary focus, with its regional lymph nodes. This conception of the development of the lesion we owe to Ghon and Hamburger, and to the work of the last-named authority at least some reference should have been made.

Such extreme enlargements of lymph nodes as are illustrated in this book are uncommon in infants and young children in England. When the primary focus is invisible these minor lymph node enlargements may indicate possible localisation of the primary focus. As Parrot put it—these lymph nodes act as "mirrors of the lungs." In common with other American workers, Dr. Stoloff apparently devotes much attention to the radiological study of the more acute chest conditions, particularly the pneumonias. He reproduces interesting serial radiograms of a ition arising in the course of pneumonia, which alls "aseptic" or "aputrid" necrosis.

is is a most comprehensive work deserving close y.

ent Advances in Organic Chemistry.

xth edition. By ALFRED W. STEWART, D.Sc., ofessor of Chemistry in the Queen's University Belfast. London: Longmans, Green and Co. 31. In two volumes. Pp. 421 and 432. 21s. ch volume.

o all interested in the development of organic nistry these summaries by Prof. Stewart are luable; his style is always lucid and his choice material excellent. The first volume contains ter suitable for third-year students and forms ntroduction to the second which is intended for ours students and post-graduate workers. Vol. I. s with a short historical survey of the main of progress of organic chemistry in the latter of the nineteenth century while the first chapter ol. II. deals with the advances of the last 25 years. ongst the fresh subjects treated are several of rest to the pure organic chemist such as strainless on rings and a number of terpenes and alkaloids. lical readers will look in vain for summaries of chemistry of the vitamins, hormones, and allied stances.

antitative Organic Microanalysis.

y FRITZ PREGL, D.Sc., Ph.D., Professor of Medicinal hemistry; Principal of the Medico-Chemical nstitute of the University of Graz. Second English dition translated from the third revised and nlarged German edition, by ERNEST FYLEMAN, .Sc., Ph.D., F.I.C., Consulting Chemist, Sutton, urrey. London: J. and A. Churchill. Pp. 237. 15s.

HE methods of Prof. Pregl are so well known as to be regarded as classical. The English trans- ion of his book, which appeared some years ago, ame authoritative among works on quantitative anic analysis. In the third German edition which Dr. Fyleman's present translation is based, ny of the chapters have been rewritten, and it is rticularly interesting to see that Prof. Pregl has wn good judgment in selecting for revision just se which contained matters puzzling to the ginner. He has added an interesting and important tion on the identification of organic compounds d groups. The work is a very valuable one and the nslation is good.

ext-book of General Bacteriology.

Tenth edition. By EDWIN O. JORDAN, Ph.D., Professor of Bacteriology in the University of Chicago and in Rush Medical College. London: W. B. Saunders Co., Ltd. 1931. Pp. 819. 28s.

GOOD text-books, unlike old soldiers, are not mortal. A few, in the hands of succeeding genera- ons of editors, seem continuously to renew their outh but it is the fate of the majority that, after ourishing for a certain period, they appear no more. his is not really strange, for it is often a harder task revise a book effectively than it can ever have been write it. The introduction of new matter into an isting framework and the adaptation of chapters hich must be modified, and yet are too good to be crificed and rewritten, imposes a great strain pon the ingenuity, common-sense, and pride of an author; so that as a book ages it often degenerates from a continued narrative into something of a scrap-book and thus passes to its doom. No such improvisations and makeshift alterations are to be found in Jordan's text-book. It remains a most admirably lucid exposition of this subject; short, concise, yet covering a wider field than most text-books of bacteriology which come into the hands of medical students. One of its major virtues is that subjects on the edge of medical bacteriology, and those verging towards the more technical aspects of the subject, are especially well treated. Certain criticisms might be made. The important subject of bacterial variation is barely touched upon, whilst the use of the term "phase" in speaking of the $S \rightleftharpoons R$ states is unfortunate, since it has been widely adopted, at least in this country, for the H-antigenic type and group states of certain Salmonella which were discovered by Andrewes. The type of filter illustrated in Fig. 43 is not one in common use, whilst the sense in which the term "mixed and secondary" infections (p. 143) is employed is hardly the usual one. Such blemishes are few and are not serious.

This is indeed a fine mellow book, well balanced pleasant to read, and beautifully produced.

Experimental Syphilis and Framboesia.

With Special Reference to the Comparative Pathology and Immunology. By S. MATSUMOTO, Professor of Dermatology and Syphilology, Kyoto Imperial University. Kyoto: Instit. Dermatosyphil. Universitas. Imperialis. Pp. 408.

IN this monograph the results of work on experimental syphilis in rabbits, including the comparative study of framboesia and other spirochætoses are fully described by Dr. Matsumoto. The first part of the work is devoted to an exhaustive account of the macroscopical and microscopical appearances of the diseases considered, while the second part is concerned with immunity in rabbit and mouse spirochætoses. The author states that his purpose in publishing these experimental results is to show the basis on which his theories of "syphilis immunity" are founded. He developed this theory in a communication to the Eighth Congress for Dermatology and Syphilology held in Copenhagen on August 6th last. An interesting terminal section on sero-chemical changes is included. The monograph is illustrated by excellent photographs.

Sevenoaks Essays.

By GORDON WARD, M.D. London: Metcalfe and Cooper, Ltd. 1931. Pp. 316.

DR. Gordon Ward in this collection of interesting and amusing essays is helping to discharge a national task—namely, the preservation of local records necessary for the historical understanding of much of our social environment to-day. The chapters represent gleanings from a large number o old documents which, for the most part, have found their way to the public library at Sevenoaks; no area is dealt with except that of the Sevenoaks Urban and District Councils or, in more ancient parlance, of the three Hundreds of Codsheath, Westerham, and Somerden. The limits thus laid down for himself by the author have been generously interpreted, for the material is of the most heterogeneous description, dealing now with the careers of local worthies, now with Roman remains, now with the construction of palaces, and now with the demolition of cottages; we meet with kings and earls, yeomen and peasants, villains and eccentrics. An interesting little chapter on "beating the bounds" sets out examples of the curious landmarks that were employed to mark parish areas in comparatively recent times; several chapters describe interesting legal proceedings and others give amusing biographical and topographical information, when the preservation of the ancient spellings often gives force to the remarks.

Dr. Ward's object in writing this book has been to awaken interest in the study of old records and quicken efforts to preserve them, inasmuch as the contents of muniment rooms and other storage places are often in danger of destruction. Experience has shown that from such material the real history of the countryside can be gathered, while, as this volume shows, apparently dry-as-dust documents can be made interesting to the general public if the editor of their contents has the skill necessary for the work. Dr. Ward urges all who have documents of local interest to imitate the example of Lord Middleton who has given to the Sevenoaks library much that has found its way into this compilation.

Only one medical character receives more than a casual reference, and that is Dr. Thomas Fuller whose Latin epitaph can be read in St. Nicholas Church. He died two hundred years ago, and he wrote in the latter phase of his long life "Pharmacopœia Extemporanea, or a Body of Prescripts, in which Form of Select Remedies, accommodated to most Intentions of Cure usually occurring in Practice . . . and so on," from whose pages amusing and nauseating quotations are sometimes met with. He also wrote a book upon eruptive fevers, in which he pointed out how to diagnose flea-bites. The last of the Bosvilles of Bradbourne, a very old local family, made a curious will which has a medical interest. He lost the whole property by gambling, regained it presumably in similar manner, stopped play for ever and willed the property, first to a clerk in the India Office who had been polite in the payment of dividends, and then to his medical adviser.

The Scientific Detective and the Expert Witness.

By C. AINSWORTH MITCHELL, D.Sc.Oxf. Cambridge: W. Heffer and Sons, Ltd. 1931. Pp. 242. 3s. 6d.

THE machinations of the criminal and the investigations of the detective, professional or amateur, have become for the last few years a subject of highly popular interest, quite a proportion of popular reading for pleasure being represented in the pages of what are inclusively termed "shockers." The literary quality of these stories is extremely varied, being with some of the authors really high, and with a larger fraction quite low, but apparently readers medical or lay, may derive thrill or shock from each class, without feeling the difference. Indeed, the medical reader may now and again find in the most slovenly production, ingenious adaptations of medical and scientific possibilities together with audacious impossibilities, and, when preposterous episodes are detailed because a good story could not get on without them, gratitude is due to the author. But medical readers resent exercises of sheer fancy, when accompanied by detraction of their profession. This resentment is justified with monotonous frequency.

Dr. Ainsworth Mitchell has written a handbook which might serve as a source of inspiration to the intending parents of a shocker, for the plots of admirable stories of the kind will be found in his pages; he has provided a book of reference from which these authors could obtain exact instruction as to what they can and what they cannot make a villain do, while still conforming to right principles of science. The book contains an interesting chapter on graphology. Experts in handwriting have come in for a full share of the strictures that have been passed upon expert evidence in general, but Dr. Mitchell, in recording the work mainly of an American, Mr. A. S. Osborn, lays down rules for the detection of the forger of a very practical sort. The slips which the forger might make are so definitely pointed out that the publication of the information might be held to be dangerous. A criminal, who knew beforehand what are likely to be the main points of resemblance and the main points of difference brought forward, in a comparison of a genuine with a false document, would be on the alert to see that his fabrication passed the tests of such a parallel investigation.

ERRATUM.—On page 87 of our issue of Jan. 9th, in a review of Kessler's "Accidental Injuries," the number of pages is given as 71, the last figure having dropped out. The actual number of pages in the volume is 718.

REPORTS AND ANALYSES

RYVITA FLAKES.

(RYVITA CO. LTD., 96, SOUTHWARK-STREET, S.E.1.)

THE flakes are prepared from rye of the best quality by a heating process in which the starch, ordinarily insoluble, is rendered soluble, and is thereby easily digested and assimilated.

When analysed the flakes were found to have the composition :—

Carbohydrates (altered or dextrinised starch)	78·94	per cent.
Protein (N × 6·25)	9·60	„ „
Moisture	6·80	„ „
Crude fibre	1·72	„ „
Fat	1·40	„ „
Ash	1·54	„ „
Calorie value per lb.	1707	

Nearly one-fifth of the material is soluble in cold water, indicating that the dextrinising process has been carried to a considerable extent.

The Ryvita flakes have an agreeable and palatable flavour; they may be consumed in a variety of ways, and constitute a new and useful addition to a light diet.

PRECAUTIONS AGAINST INFLUENZA IN IRELAND.—The Department of Local Government and Public Health of the Irish Free State has issued a circular-letter to the various local health authorities dealing with the precautions th should be taken to prevent the spread of influenza. Sanitar authorities are advised to formulate schemes for dealing with outbreaks of the disease, should they occur, and these schemes should include the coördination of medical and nursing facilities. Consideration should be given to the provision of hospital accommodation for severe cases. Acute primary pneumonia and influenzal pneumonia are already compulsorily notifiable, and the Department suggests that a system of voluntary notification of influenza should be established. The letter goes on to point out the usual modes of transmission of the infection of influenza by coughing, sneezing, loud talking, and warns against crowding in public resorts or public vehicles. Children from infected houses should not be allowed to attend school, and cases should be isolated if possible.

The SPECIFIC OVARIAN HORMONE

which normally controls and activates the menstrual cycle

SISTOMENSIN

standardised physiologically

dysmenorrhœa, menorrhagia, hæmorrhages of puberty and menopause, hypoplasia of the uterus, disturbances subsequent to menopause or oöphorectomy.

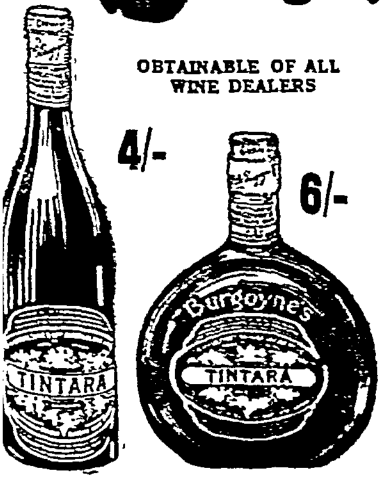
AN EMPIRE PRODUCTION

OF GREAT VALUE TO THE INVALID

Burgoyne's

Tintara

Ferruginous



OBTAINABLE OF ALL WINE DEALERS

4/-

6/-

THIS PURE AUSTRALIAN WINE introduced in 1871, has been highly recommended by the Medical Profession in all cases where strength and nerve force have required building up. In anæmia, debility, neurasthenia, and in convalescence after any illness, this full-bodied, generous wine, palatable as well as health producing, has proved itself the finest of all natural stimulants

Sample Bottle sent free in the United Kingdom, on receipt of professional card.

ABSOLUTELY PURE

P. B. BURGOYNE & CO., Ltd.,
Burgoyne House, Dowgate Hill, London.

PRODUCTS OF THE GLAXO LABORATORIES

Ostelin vitamin D LIQUID

By means of Ostelin Liquid, the practitioner can prescribe vitamin D in strictly controlled amounts. It is a tasteless, odourless, glycerin suspension of irradiated ergosterol. It is miscible with water. It can be prescribed in mixtures.

In 8 c.c. phials ... 2/6
Other sizes for dispensing.

A guarantee of purity and biological potency...

Every preparation that bears the Glaxo Laboratories device has been subjected, at every stage of its manufacture, to rigorous scientific and technical control.

It has, moreover, been assayed by one or more of the most precise chemical or physiological methods available, the results being expressed, wherever possible, in terms of recognised units.

The "G.L. Device"

represents a pure, biologically potent, and accurately standardised preparation of the Glaxo Laboratories.

GLAXO
LABORATORIES,
56 Osnaburgh Street,
LONDON, N.W.1.

Colloidal Calcium with Ostelin vitamin D

For chilblains, a School Medical Officer has described subcutaneous injection of Ostelin and Colloidal Calcium as a specific treatment. Extensive clinical tests have shown it to be equally valuable as a prophylactic.

In boxes of six 1 c.c. ampoules 5/-.
In 1 oz. bottles 10/-.

ADEXOLIN CAPSULES

Vitamins A and D highly concentrated.

In acute infections, Adexolin brings the temperature and pulse rate down, and enhances resistance. It serves also to protect patients liable to frequently recurring colds, influenza and to infections of the respiratory tract.

Boxes of 25 Capsules 3/9 each
Boxes of 100 Capsules 12/6 each

ANTIVIRUS Preparations

'Antivirin' Brand

The results of antivirus therapy in several conditions are frequently described as "remarkable."

Full particulars, with prices, of the Antivirin series will be sent on request.

Staphylococcus Antivirus.
Streptococcus Antivirus.
Staphylococcus and Streptococcus Mixed Antivirus.
B. Acnes Antivirus Ointment.

OSTOMALT

Vitamins A, B, C and D—rigidly standardised—in a readily assimilable and appetising preparation. A trustworthy supplementary source of vitamin C. For convalescent or otherwise debilitated adults and children, Ostomalt serves as an ideal tonic food, stimulating the appetite for other kinds of nourishment.

In ½-lb jars ... 2/6
In 1-lb jars ... 4/-

GLUCOSE-D

A preparation of medicinal glucose in which is incorporated calcium glycerophosphate and vitamin D to assist a normal metabolism of calcium and phosphorus in conditions—notably acidosis, asthma, cyclical vomiting, heart disease, and fever—that may require both glucose therapy and the prolonged administration of a fat free, and thence fat-soluble-vitamin free, diet.

In 1-lb tins—1/9

THE LANCET.

NDON: SATURDAY, JANUARY 16, 1932.

HE PHYSICAL BASIS OF EDUCATION.

the last meeting of the Medical Officers of ls Association a discussion took place on cal education in schools, which is reported r columns this week. The debate was prac- nd timely. For it is held by those who have ht about the matter in its many aspects— o every member of the medical profession ubject appeals from one angle or another— case has been made out for recognising that tion, private and national, should take a frank account of physical and physiological derations. This was the thesis of an address tly delivered before the North of England ation Conference in Nottingham by Dr. R. H. LEY, a senior medical officer of the Board of ation, who showed that during the last 25 the term "physical basis of education" has ved a huge extension of meaning. By the close e last century some public appreciation had ed that it was largely futile, and might even human, to impose systematic education on ren suffering from such disabilities as hunger, defective eyesight, adenoid overgrowths and l infections, or physical exhaustion from oyment out of school time. Such children provide a physical basis of a most unsatis- ry kind for education, and the prevention treatment of obvious and gross defects have the object of strenuous work over the period tioned—work which has been rewarded by tantial successes, as the annual evidence of ical officers of health and summarising reports e Board of Education have been able to prove, detailed figures in support of optimistic ions. The risk is that we should be too readily ent with happy achievement and be slow to eive that medical inspection must now mean eat deal more than the detection and treatment nanifest physical disabilities. While it is true t the majority of children in the course of lical inspection can be passed on for treatment h little or no comment, there are many others re inspection in the school is the beginning y of our medical responsibility towards them. ing eyesight as an example; we may quote CROWLEY. He says: "We must no longer be tent with finding out by somewhat rough and dy means what defect of eyesight a child may e and then send him to the oculist for treatment. is is analogous to what we used to do with the cripple child, and to what we still do in a large measure with the child with heart disease, though our practice in this respect shows we are learning the lesson the cripple child has taught us. More careful inspection of the visual capacity of the young child is the necessary precursor to any more effective prevention of defective eyesight, and to understanding of healthy vision." Now the understanding of healthy vision is linked up not only with the physiology of the child, but with the academic curriculum which he undergoes, and his material environment, and similarly we have come to perceive that the physical basis of education has always these large implications.

The discussion before the Medical Officers of Schools Association and Dr. CROWLEY's address at Nottingham are both illuminated by a correspondence which has been running sporadically through the columns of the *Times* for the past three months. This correspondence started in a challenging speech made by Lord DAWSON at the opening, last October, of the new sanatorium at Epsom College, when he pointed out that the medical officers of schools, and doctors called in attendance upon schoolboys, might well make a study of the principles of physical education, their duties not being limited to the care of the sick. On this text medical officers of schools, headmasters, instructors of physical training, parents as represented by the Parents Association, the Schoolmasters Education Association, and other representative individuals and groups have been expressing many views, mostly concordant, and, when otherwise, supplying arguments in support of their words. From these letters one message emerges, which can be summarised in the phrase with which Mr. MORTIMER BOOTH, the physical instructor at Christ's Hospital, opened the debate before the Medical Officers of Schools Association, when he pointed out that the relation of the physical to the mental development of the boy must always be kept in mind. The Consultative Committee of the Board of Education have issued valuable reports on "The Primary School" and on "The Education of the Adolescent," which imply or indicate the need for basing the process of education from early years upwards upon a physiological basis. That we have been getting nearer to this attitude for the last 50 years is sure, and as a practical development Dr. CROWLEY now makes the suggestion that special educational methods should be adopted for children between the ages of 7 and 11, believing that the characteristics of this age-group have a particular significance, it being a period of comparative stability, of resistance to unfavourable conditions, and of consolidation of muscles and nerve connexions. This is a period in the child's life which precedes the time when physical education usually becomes part of educational routine—definitely it is a period anterior to public school life; it is therefore useful to be reminded that "adolescence has its roots as well as its fruits."

To provide a physical basis for education is not

---

[1] THE LANCET, 1931, ii, 807.

only to see that the calls for adequate food, proper ventilation, and due opportunities for exercise are well met. It is to see that throughout the education period there is an environment provided which will give physical education its proper chance, so that, in reciprocity, the educational curriculum may yield good results. A public sentiment is needed that good physical conditions are not so much a basis upon which education should be founded as a natural concomitant with which education must proceed. The recent letters in the *Times*, and various articles and reports which form stock reading in our columns, show that to secure this harmonious situation certain differences of opinion have to be smoothed out, but the process should not be hard. There are at the present moment points at issue between persons who have a right to consider themselves and to be considered of equal authority. Drill upon the Army pattern is spoken highly of, on one hand, as the kindergarten of physical organisation, and, on the other, is stigmatised as dull drudgery. Mr. JACKS, the headmaster of Mill Hill School, whose opinion carries weight in all educational circles, considers that, while a department should be created for the provision of adequate physical instructors, the school doctor, though an essential partner, should not be in charge of the department; this is a view running counter to that expressed by Dr. MURRAY LEVICK, who is an equally experienced counsellor. In the shaping of sanitary environment the medical officer of the school would naturally advise the authorities concerning heating and ventilation of premises, while his estimates of the quality of the children's food and the duration and pattern of their hours of study should be taken into account. In the shaping of physical education his position as an essential partner with the instructor might be easy to define; but it is hard to allot him a more definite position than that of an intelligent friend, when it comes to the arrangement with housemasters and headmasters of the details of housekeeping or the time-sheets of study. We are speaking here, of course, of the public schools, and there is nothing even in those strongholds of individualism that should not be capable of adjustment between persons having before them the common object of benefiting youth; in the State schools the same difficulties would not arise. Coöperative work between the school doctor and the physical instructor will be advanced by the better opportunities that are now being offered to the latter. The University of London has instituted a special diploma for physical education, which is open to candidates from approved centres, and the possession of the diploma will give the physical instructor a proper academic position on the staff of his institution. At the same time the Trustees of the Carnegie United Kingdom Trust have discussed the situation with representatives of local educational bodies and with the Board of Education and the resulting developments at Leeds are full of promise. From all of which it is to be seen that the need for a physical basis in our educational organisation is now not only admitted but being met along many practical lines.

THE SURGICAL REVOLUTION.

SURGEONS of long experience, when they contemplate the methods which were in vogue during the early years of their career, cannot fail to be impressed with the complete change in the outlook for many patients who must of necessity submit to an operation. Prostatectomy was at one time an extremely hazardous procedure; cholecystectomy was a dangerous undertaking, gastrectomy exacted a heavy toll; whilst thyroidectomy for exophthalmic goitre was so full of risk that it practically had no place in surgery. With respect to all these operations the prognosis has entirely altered, and it is instructive to ponder the factors which have brought about such astonishing advances. Refinement in technique has no doubt played its part, but modern surgeons would hardly claim to be better craftsmen than such masters as BILLROTH, DOYEN, or HORSLEY. It is likely that the greatest factor is the change in our mental attitude towards operation—notably a realisation that mechanical factors do not always play a major part, and often a very small part, in the restoration of the patient to health. Anatomy is as essential as ever, but physiology and the reaction of vital processes to altered mechanical relations have become recognised as of supreme import. Gastro-jejunostomy, for example, is more than a drainage operation, and the retention of urine due to an enlarged prostate has far more momentous effects upon kidney function than the mere mechanical distension of the renal pelvis. The study of the alteration of function of vital organs, the demonstration of the great reserve strength they possess, and the development of means of restoring their activity have placed in the surgeon's hands precautionary measures of immeasurable value. There has grown up a system of treatment before and after operation which is based upon solid foundations.

The extent to which modern surgical practice has been influenced by the development of our knowledge of physiology and pathology is made clear in the comprehensive series of articles by Dr. R. A. CUTTING on the principles of pre-operative and post-operative treatment which have been appearing during 1931 in the *American Journal of Surgery*. The format and double pagination of these articles, of which the last was published in the December issue of the journal, show that they are designed to form a book, and the volume will be a welcome addition to surgical literature. The last section of the work contains chapters on extensive superficial burns, on acute traumatic cranio-cerebral injuries, and on intestinal obstruction. In connexion with severe burns emphasis is laid on need for treatment of shock by morphine in large dosage, by the maintenance of heat, and by the promotion of quiet and rest. The local trauma is relatively unimportant, as far as immediate treatment is concerned, since toxic absorption does not occur for several hours. For extensive superficial burns tannic acid is recommended to the exclusion of any other local application. Its advantages in preventing the develop-it of toxæmia are stressed, but Dr. Cutting s not pretend that the coagulation of toxins be relied on to make systemic treatment ecessary. Blood transfusion, the administra- of saline solution in large quantities (4000 5000 c.cm.), and of dextrose are called for in re cases, supplemented perhaps by such iation as can be provided from an electric t tent, the use of which is recommended on r grounds. In the treatment of head injuries, ntion is drawn especially to the relative ortance of injuries to the contents of the skull the relative unimportance of skull fractures such. The interpretation of symptoms on the is of the pathological physiology is outlined, and non-surgical treatment of increased intra-nial pressure by dehydration and by lumbar cture is discussed as well as the indications for ecompression operation. The chapter on ileus ather disappointing, for Dr. Cutting can give little new information on the prophylactic curative treatment of this condition, or in the atment of the toxæmia of ileus, which is still ost entirely symptomatic. But he does show the patient's discomfort can be relieved, and kes a useful point in drawing attention to the ility of using epinephrin or ephedrine in con-ction with splanchnic or spinal analgesia for relief of ileus, since these drugs overcome the ect of the analgesia.[1]

No better instances of the advances in pre-erative and post-operative treatment could be en than the strides which have been made in surgery of diabetes and the hypertrophied ostate which Dr. Cutting dealt with in a previous ntribution to the series. Not many years ago e smallest surgical intervention in a diabetic s looked upon with horror and apprehension, about 50 per cent. of the patients died. Now e mortality is less than 5 per cent. This has en brought about by: (1) standardising the diet each particular patient; (2) giving an adequate se of insulin; (3) encouraging the patient take food almost up to the time of the operation, starvation leads to ketosis; (4) giving a pre-erative dose of dextrose together with a sufficient nount of insulin; (5) using minimal amounts of æsthetic, never chloroform, preferably nitrous xide, and best of all a local anæsthetic; (6) giving dextrose, after operation, all of which measures re the outcome of physiological experiment in nimals and chemical investigations of the blood man.

The patient with an enlarged prostate is lways in the later decades of life, and the evitable degenerations have occurred in his irculatory and other essential systems. Their ffect has been increased by urinary retention, with he toxæmia it produces. The remarkable reserve ower which the kidneys are known to possess nay be all but used up before the patient is aware hat anything is amiss, but the degree of danger an be estimated by means of two routine tests: 1) the power of concentrating urea in the urine, and (2) the level of urea in the blood. So far as the kidneys are concerned it is now known that if the pressure against which they have to secrete is gradually lowered, latent powers of recovery are allowed play, and renal function will return to normal or nearly normal level, often with surprising speed. This discovery formed the basis for the two-stage operation which has saved innumerable lives. The performance of a preliminary operation to gain this end, however, is now regarded as unnecessary by an increasing number of surgeons, for it has been proved that catheter drainage is as effective as a suprapubic opening in more than three-quarters of the cases. The problem of the damaged kidney has thus been largely solved. It is not so with some of the other disturbances, which may be present in patients with prostatic enlargement. Every effort should be made to estimate the condition of the cardiac muscle; for this, unfortunately, no very reliable test is as yet available. A hæmoglobin estimation should be carried out. The chronic interstitial nephritis from which all these patients suffer causes an anæmia which is the more serious inasmuch as the amount of hæmorrhage during the operation, and subsequently, cannot be foretold or certainly controlled. Enough has been said to show that slowly yet surely a revolution has been taking place in surgical outlook, surgical treatment, and surgical prognosis. This is true of every province of surgery. The cruel withholding of fluids after laparotomy, the painful, unnecessary, and harmful purging both before and after operation, the unkindly restraint, are things of the past. The sufferer from an abdominal complaint necessitating a surgical operation may well be thankful he was not born 50 years before.

THE LICENSING COMMISSION.

The Report of the Royal Commission on Licensing is an interesting and a surprising document. The surprising feature is the degree of unanimity achieved by a body selected to include extremes of temperance and trade opinion in addition to other members who might have been expected to hold preconceived ideas on the subject. The result is a tribute not only to the able chairmanship of Lord Amulree, but also to the strength of the evidence which brought 16 out of 19 members into the fold of the Majority Report. Of the three Minority Reports, one, that of Mrs. Simon, is *in substantial agreement* with most of the conclusions of the majority, but would go more quickly in the direction of the public ownership to which the Majority Report quite definitely points. The other two Minority Reports are those of one of the brewing trade representatives and of the retailers' representative respectively. Another representative of the liquor trade, also a brewer, signs the Majority Report with certain reservations.

When the Commission was appointed in 1929 it was suggested, not in pro-trade quarters alone, that the Labour Government had successfully shelved the question because so diverse a team would never produce any effective result. Events have certainly saved the Labour Government the trouble of dealing with the Report which, however, *completely* belies those *anticipations*. The Report is likely to form the basis of legislation in the future to a greater or less extent according to the character of the Government which eventually tackles the problem. It is certainly unlikely that the present Government will find time for legislation on the lines of the Report.

---

[1] Ochsner, A., Gage, I. M., and Cutting, R. A.: Jour. Amer. Med. Assoc., 1928, xc., 1847.

After giving full weight to the great general improvement in sobriety which has taken place during the present century, and particularly since the war, the Report states that excessive drinking still persists in large measure, and that apart from actual intemperance, expenditure on intoxicants still reaches a definitely uneconomic figure. Some startling figures are mentioned in support of the latter contention. The annual expenditure on drink in an industrial metropolitan borough was stated in evidence to be reliably estimated at £1,200,000 or an amount of 16*s.* per week for each family, and £17 per annum for every adult over 20. *This in a borough where the average employed* wage is put at approximately £2 5*s.* a week. The problem, then, is still substantial, and in the forefront of the proposals for improvement the Report places "the provision of machinery for achieving much more rapid reduction of licences—"more rapid, that is, than has been achieved by the 1904 Act. This is to be brought about by, inter *alia*, an increase of the levy up to a maximum of three times the existing rate. It is satisfactory to observe that the Report particularly stresses the need for "more effective encouragement and more rapid development of the policy of public-house improvement, and in particular of the conception of the public-house as a place of general refreshment *rather than as a place primarily devoted to* the sale of alcohol." This is a policy which will be warmly approved by public opinion generally, and it is of great interest to note that, after fully reviewing the relative advantages and disadvantages of private enterprise and public ownership more particularly in relation to the policy above defined, the Report comes down on the side of public ownership, though it is on this point that certain of its signatories append reservations. The line of agreement by which the majority arrive at their conclusion is illustrated by the following quotation:—

> "While recognising fully the efforts of the best elements in the Trade to improve their houses in accordance with modern ideas and tendencies . . . it is impossible to get away from the fact that the ruling motive of the brewer, who is the owner of the vast majority of existing publichouses, must necessarily be *promotion of the sale of the goods* in which he is chiefly interested; and it would be unnatural to expect the Trade as a whole, left to itself, to lead public opinion in the matter of the conversion of the publichouse into a place where the sale of intoxicants is to take a secondary position."

The financial circumstances of the time are held to preclude universal State acquisition of the liquor trade at present, but extension of public ownership is recommended though not on precisely the lines existing in the Carlisle area. The suggestion is probably wise that direct State management should be modified in the direction of management by a body established as nearly as possible on business lines but with due provision for the *element of social welfare.* Mrs. SIMON's Minority Report is of special interest in this connexion presenting, as it does, a comprehensive scheme for public ownership which appears to surmount the two objections most commonly urged against that course, viz., (1) the burden on the exchequer of cash payments or guarantees of vast sums, and (2) direct State management of the liquor business The London Passenger Transport Bill is the model on which the scheme is based, payment for the interests taken over to be made in the form of "Licensing Stock." The essential feature of the scheme, says Mrs. SIMON, "is the transfer of the control of the sale of alcoholic liquor from the private interests in which it is at present vested to a Statutory Body constituted for the purpose by Parliament but not in itself a State Department."

Another matter of general interest dealt with in the Majority Report is that of permitted hours of sale. Restriction in hours of sale was first introduced *as a war measure, and after* recording the conviction that restriction has been of great value in promoting sobriety the Report states the *considered opinion that* the present scheme is acceptable to a vast section of the public, including public-house clients, and is becoming more and not less so. This represents a significant change in public opinion which is likely to support the proposal of the Report that the general closing hour should be 10 P.M., subject *to* the provision of special facilities in restaurants and hotels, especially in London theatre-land. The scheme proposed to meet such cases appears both reasonable and workable. Regarding clubs, the Report favours a considerable tightening up of the present law, *and, if adopted, the recommendations* will do much to remedy an admitted abuse. It is regarded as indispensable that powers of entry into registered clubs should be conferred on the police, and that among *the* essential conditions precedent to registration is to be the absence of any "tie." The Report suggests that well-conducted clubs should not resent a control which without embarrassing them will assist in eliminating undesirable clubs The tied house system as a whole comes in fo severe criticism, and modifications of the law ar suggested in the direction of improving the positio *of the licensee vis-à-vis the owner-brewer.* Thes *recommendations, if* carried into effect, should d much to secure improved service for the public Few will be found to quarrel with the desir expressed in the Report for more definite encou agement of specific *education on the* subject alcohol, but the *present time is hardly* propitiou for the execution of the only one of the main recom mendations which has *not, so far,* been referred to— viz., the proposal for the establishment of National Licensing Commission. Nevertheless, th case for this proposal, like all the other recommen dations in the Report, is *moderately* set out an so impartially *argued that* it should receive ver careful *consideration.* The Report will be welcomed by all who are genuinely seeking an advance in th highly important matter of temperance reform.

ANNOTATIONS

ERRORS IN CERTIFICATION.

three cases, summarised in another column, the t Sussex Insurance Committee has recently found titioners at fault for issuing certificates con- ing false and misleading statements. In each he had given a series of monthly certificates, on special forms provided for the purpose, stating t he had examined the patient on a particular date ugh he had in fact not seen the patient profession- during the period covered by the certificates. it happened, no great harm was done. In each e the patient was suffering from chronic disease ich caused incapacity for work during the period. each case the practitioner was justified in issuing ecial monthly certificates. In no case was the proved society prejudiced by the payment of nefit following upon the certification of continuing apacity. In no case was the practitioner asked visit the patient. In no case was treatment quired to alleviate pain or to prevent suffering. In no se was there much, if any, prospect of active treat- ent arresting disease. Fortunately it is clear that ese three cases were not the most serious imaginable. ut it is equally clear that any inaccurate certification serious enough at a time when supervision over the istribution of millions of pounds in sickness and isablement benefit should more than ever be unctiliously exercised. These great sums are dispersed rgely upon the evidence of insurance practitioners' ertificates.

National health insurance certification is neither a rivial formality nor a merely clerical matter. The ood-natured desire to avoid giving trouble looks udicrously inadequate if, when the facts almost nevitably come to light, it is the only available xplanation for the untrue statement that a doctor has examined a patient. If insurance work is under- aken, the game must be played according to the rules. ne rule requires a periodical certificate to be given on a special form; the form incorporates a declaration that the certifying doctor has examined the patient. At present our fellow-citizens are prepared to accept a medical practitioner's signature as a guarantee that the certified statements may be relied upon as truthful. While it is easy to be pontifical at the expense of hard-worked panel doctors, we ask them not to let these cases recur. No special "Warning Notice" is needed by way of reminder that, if our guarantees cease to be worth their face value, the consequences must be grave both for the individual and for the whole profession.

PANCREATIC TUMOURS AND HYPOGLYCÆMIA

AN apparently normal pancreas is a common nough finding at autopsy in fatal cases of diabetes, with the ordinary histological methods usually ployed a microscopical examination may show no signs of disease. In fact, there may be less structural change to account for prolonged and serious symptoms in diabetes than in any other chronic disease. In the current number of the *American Journal of Pathology* (1931, vii., 723) Dr. Margaret G. Smith and Dr. Marshall G. Seibel suggest that anatomical evidence of the association of the pancreas with carbohydrate metabolism may be forthcoming more frequently than is usually supposed. In 1927 R. M. Wilder and his collaborators published a remarkable case of carcinoma of the islands of the pancreas associated with hyperinsulism and hypoglycæmia. The patient required hourly doses of glucose to prevent hypoglycæmic convulsions, and when the necessary sugar was delayed the blood-sugar fell below 0·03 per cent. Only a few other examples of island tumours have been reported in the literature, but Dr. Smith and Dr. Seibel suggest that they are not really uncommon. They themselves describe five cases. In four of them the tumours were quite small, 1 cm. or less in diameter, and might well have been overlooked. The fifth case was apparently diagnosed in life; it was at any rate removed by operation from a young boy who had shown characteristic symptoms of hypoglycæmia for eighteen months. This tumour was situated in the body of the pancreas and measured 2 by 1·5 cm. Of the other cases, one showed signs of hypoglycæmia and the blood-sugar estimated just before death was 58 mg. per 100 c.cm.; another, who died from pulmonary embolism following lobar pneumonia, behaved like a total diabetic during her last illness. The remaining two presented no very definite signs of a pancreatic lesion during life. Some of the previously recorded cases have been described as low-grade carcinomata, and Wilder's tumour had disseminated to the liver and lymph nodes; but Dr. Smith and Dr. Seibel regard their tumours as adenomata, and from the descriptions given none of them appears to show any evidence of malignancy. There seems no doubt that they are composed of island cells and consist largely of abnormal beta cells, but it is interesting to note that of two cases which presented tumours identical macroscopically and microscopically, one showed signs of hypoglycæmia, while the other gave no evidence at all of disordered metabolism. Whether it secretes insulin or not the tumour appears to have no stimulating influence on the normal island cells in the rest of the gland; these, anatomically, are quite unaltered, though clinical studies of the sugar tolerance suggest that in some cases their activity may be depressed.

BRITISH SPAS AND SEASIDE RESORTS.

THE primary purpose for which the Medical Directory is consulted is reference to personnel—and the very bulk of the sections devoted to British doctors is liable to obscure the other matter. One of the sections, which contains a medical report on British spas and seaside resorts, by Dr. R. Fortescue Fox, has been reprinted as a pamphlet,[1] in which convenient form it reveals a message peculiarly appropriate to the present times. Excluding the New Zealand spas—which in a future edition might well be supplemented by spas in the other Dominions or omitted—some 130 spas and health resorts are dealt with. These are indexed alphabetically from Aberdovey to Yarmouth, but in the text are classified into the following subsections: The Principal British Spas (11); Other Inland Health Resorts (26); Health Resorts of the British Coasts: North-Western Group (23); South-Western Group (23); Southern Group (13); South-Eastern Group (13); Eastern Group (20). The information given includes some account of the situation and climate, season, natural waters (where these exist), sea-bathing in coastal resorts, medical indications, and brief notes on the accommodation available, with references to the advertisement pages have certainly saved the Labour Government the trouble of dealing with the Report which, however, completely belies those anticipations. The Report is likely to form the basis of legislation in the future to a greater or less extent according to the character of the Government which eventually tackles the problem. It is certainly unlikely that the present Government will find time for legislation on the lines of the Report.

---

[1] London: J. and A. Churchill 1931. Pp. 95. 1s.

After giving full weight to the great general improvement in sobriety which has taken place during the present century, and particularly since the war, the Report states that excessive drinking still persists in large measure, and that apart from actual intemperance, expenditure on intoxicants still reaches a definitely uneconomic figure. Some startling figures are mentioned in support of the latter contention. The annual expenditure on drink in an industrial metropolitan borough was stated in evidence to be reliably estimated at £1,200,000 or an amount of 16*s.* per week for each family, and £17 per annum for every adult over 20. This in a borough where the average employed wage is put at approximately £2 5*s.* a week. The problem, then, is still substantial, and in the forefront of the proposals for improvement the Report places "the provision of machinery for achieving much more rapid reduction of licences—"more rapid, that is, than has been achieved by the 1904 Act. This is to be brought about by, inter alia, an increase of the levy up to a maximum of three times the existing rate. It is satisfactory to observe that the Report particularly stresses the need for "more effective encouragement and more rapid development of the policy of public-house improvement, and in particular of the conception of the public-house as a place of general refreshment rather than as a place primarily devoted to the sale of alcohol." This is a policy which will be warmly approved by public opinion generally, and it is of great interest to note that, after fully reviewing the relative advantages and disadvantages of private enterprise and public ownership more particularly in relation to the policy above defined, the Report comes down on the side of public ownership, though it is on this point that certain of its signatories append reservations. The line of agreement by which the majority arrive at their conclusion is illustrated by the following quotation:—

> "While recognising fully the efforts of the best elements in the Trade to improve their houses in accordance with modern ideas and tendencies . . . it is impossible to get away from the fact that the ruling motive of the brewer, who is the owner of the vast majority of existing publichouses, must necessarily be promotion of the sale of the goods in which he is chiefly interested; and it would be unnatural to expect the Trade as a whole, left to itself, to lead public opinion in the matter of the conversion of the publichouse into a place where the sale of intoxicants is to take a secondary position."

The financial circumstances of the time are held to preclude universal State acquisition of the liquor trade at present, but extension of public ownership is recommended though not on precisely the lines existing in the Carlisle area. The suggestion is probably wise that direct State management should be modified in the direction of management by a body established as nearly as possible on business lines but with due provision for the element of social welfare. Mrs. SIMON's Minority Report is of special interest in this connexion, presenting, as it does, a comprehensive scheme for public ownership which appears to surmount the two objections most commonly urged against that course, viz., (1) the burden on the exchequer of cash payments or guarantees of vast sums, and (2) direct State management of the liquor business. The London Passenger Transport Bill is the model on which the scheme is based, payment for the interests taken over to be made in the form of "Licensing Stock." The essential feature of the scheme, says Mrs. SIMON, "is the transfer of the control of the sale of alcoholic liquor from the private interests in which it is at present vested to a Statutory Body constituted for the purpose by Parliament but not in itself a State Department."

Another matter of general interest dealt with in the Majority Report is that of permitted hours of sale. Restriction in hours of sale was first introduced as a war measure, and after recording the conviction that restriction has been of great value in promoting sobriety the Report states the considered opinion that the present scheme is acceptable to a vast section of the public, including public-house clients, and is becoming more and not less so. This represents a significant change in public opinion which is likely to support the proposal of the Report that the general closing hour should be 10 P.M., subject to the provision of special facilities in restaurants and hotels, especially in London theatre-land. The scheme proposed to meet such cases appears both reasonable and workable. Regarding clubs, the Report favours a considerable tightening up of the present law, and, if adopted, the recommendations will do much to remedy an admitted abuse. It is regarded as indispensable that powers of entry into registered clubs should be conferred on the police, and that among the essential conditions precedent to registration is to be the absence of any "tie." The Report suggests that well-conducted clubs should not resent a control which without embarrassing them will assist in eliminating undesirable clubs. The tied house system as a whole comes in for severe criticism, and modifications of the law are suggested in the direction of improving the position of the licensee vis-à-vis the owner-brewer. These recommendations, if carried into effect, should do much to secure improved service for the public. Few will be found to quarrel with the desire expressed in the Report for more definite encouragement of specific education on the subject of alcohol, but the present time is hardly propitious for the execution of the only one of the main recommendations which has not, so far, been referred to—viz., the proposal for the establishment of a National Licensing Commission. Nevertheless, the case for this proposal, like all the other recommendations in the Report, is moderately set out and so impartially argued that it should receive very careful consideration. The Report will be welcomed by all who are genuinely seeking an advance in the highly important matter of temperance reform.

e it is difficult to express dyspnœa quantitatively. 43 patients studied two were worse, 12 noted no erence, while 14 stated that the same exertion duced less discomfort, and 15 were cured to the ent that the ordinary exertions of everyday life sed no respiratory embarrassment. An attempt s made, in eight patients, to control these subjective ults by estimation of the vital capacity and the tilation index. Of the seven who expressed themves as better or relieved all showed a fall in the tilation index, whereas in the case of the one tient who said he was more easily dyspnœic after king digitalis the ventilation index was markedly reased. Thus from these investigations it seems at the indications for digitalis therapy in heart ease must be widened, and that many patients th troublesome symptoms might be relieved by its nely administration.

THE NON-TUBERCULOUS SILICOTIC COAL-MINER.

THE incidence of pulmonary tuberculosis among al-miners is becoming a matter of considerable nportance. For years those who have been interested n industrial pneumokoniosis have assumed that oal-miners do not suffer from any pulmonary disbility as the result of their occupation. It is true hat there is a high incidence of bronchitis among oal-miners in the later decades of life, but tuberculosis, which is recognised all the world over as the utstanding risk of those who work in dusty occupations, does not appear to occur more frequently among colliers than among other members of the population, but rather the reverse. The dust which is particularly associated with phthisis is silica, usually in the crystalline form, and it has been assumed either that coal-miners are not exposed to siliceous dusts, or, if they are, that damage to the lungs does not follow because of the protective action of the associated coal dust. Of recent years, however, it has been shown by S. Lyle Cummins and A. F. Sladden that silicosis actually does occur among men occupied in certain types of coal-mining. Why, then, is phthisis not more common among them? Silica, of course, is only one of the factors which may influence adversely the progress of a tuberculous infection; it does not necessarily constitute the whole of the story. Physical fitness and adequate nutrition may presumably be expected to act potently on the defensive side, and may do much to counterbalance the influence of the silica. Coal-mining is an arduous occupation and the physically unfit are weeded out at an early stage; while except during the recent years of depression the economic condition of the miner when in work, with all that that entails, has been above the average. But physical fitness and a high economic standard have not prevented miner's phthisis in South Africa and elsewhere, and the question why coal-miners are exempt still remains to e answered. In point of fact there is evidence that n certain coal-fields, at any rate, this freedom from tuberculosis does not obtain; and it is possible that the data upon which the statistics relating to the industry as a whole have been based have been accepted without sufficient scrutiny. The whole subject bristles with difficulties and is in urgent need of reconsideration. In a paper in a recent number of the *Journal of Hygiene*, Prof. S. Lyle Cummins and Dr. C. Weatherall[1] suggest that the coal-miner may be protected to some extent from pulmonary tuberculosis by the adsorptive power of the coal dust with which his lung is saturated. It has been demonstrated that finely divided charcoal has the power in vitro of adsorbing from tuberculin the constituent on which its activity depends. Following up this suggestion the authors have performed the following ingenious experiments. Dilute solutions of old tuberculin were saturated with powdered anthracite coal for a period of some hours. They were then centrifuged and the clear fluid was injected intradermally into adult tuberculous patients. From the difference in size of the resulting "wheals" compared with those produced by similar quantities of non-adsorbed tuberculin it was evident that the tuberculin lost a considerable degree of potency after exposure to the coal dust. In slightly alkaline solutions adsorption was considerably increased, for the treated tuberculin failed to produce wheals in 20 cases, whereas positive reactions were obtained in 18 out of 20 controls.

The question then arose whether the adsorptive power of coal dust in the lungs is the same as in the in vitro conditions, or whether exposure to the body fluids diminishes it. Coal dust was therefore suspended in fresh human blood-serum for 3½ hours. It was then centrifuged, thoroughly washed, and resuspended in the alkaline solution and used for inactivation experiments. Tuberculin adsorbed by this serum-treated coal appeared to be somewhat less active than the untreated material, but the results are nothing like as clean-cut as in the earlier experiments. It is, of course, a big assumption to suggest that the reactions occurring in these experiments are comparable with those actually taking place in the infected lung, and that carbon in the tissues will inactivate the products of the tubercle bacillus as easily as it does in the test-tube. In what must after all be regarded as a crude attempt to imitate the state of coal when actually in the lung, the authors have shown that the dust loses a great part of its absorbing power. It may well be that in the tissues it loses it altogether. As the authors say, the question can only be answered by experiments on the anthracotic animal, and in the meantime we are left with the paradox of the non-tuberculous silicotic coal-miner.

ACCIDENTS AND SICKNESS.

APPRECIATION of this interaction between environment and living beings is changing the outlook of accident prevention from the old-time concentration upon mechanical guards towards a regard for the human factor with its special sense reactions. These vary with ill-being and well-being, with the irritation bred of fatigue and the joy of healthy activity. The engineer is coming to see that accidents, far from being merely mechanical mischances, represent pathological reactions to environment; while their study is more and more laying bare to most physicians that the origin of other great causes of pathological occurrences lies as much in the environment of life as in the innate make-up of their patients. The study of "accidental occurrences" has as much to teach the physician as the engineer. The last issue of the Industrial Safety Survey,[1] published bimonthly by the International Labour Office, contains an account of the International Congress held last May at the Industrial Safety Museum in London. At this where further details are supplied by the hoteliers. This compendium of useful information is made the more valuable by the concise introductory notes, supplied by the author from his rich experience, on the choice of medicinal waters and spas, and on the general and specific indications for the selection of any spa. Dr. Fox points out that the principal considerations that may influence the practitioner in selecting a resort for a patient may be the eliminating quality of its waters, or their other qualities, the methods of external or thermal treatment provided, and the climate, amenities, and medical service. Sometimes one, sometimes another of these points predominates. At this season it is well to be reminded (page 5) that for chilly persons a course of thermal baths may have much the same stimulating effect as a change of climate, and may enable delicate workers to get comfortably through the winter. Dr. Fox adds, however, that if success is to be achieved all exposure to cold during treatment should be avoided; and that not only the bath establishments, but the hotel or dwelling-house where the "chilly person" is accommodated must be artificially warmed to summer temperature. This warning is still unheeded in too many places in this country, but an increasing number of hotels are now providing such amenities as central heating, lifts, and constant hot water in the bedrooms. The reward of installing these conveniences should be to attract many more people to follow the advice given on the cover of this pamphlet—that is, to seek the soft Atlantic airs in spring and winter, the strong Eastern airs in summer and autumn, and the sunny South coast in all seasons.

IS CANCER PREVENTABLE?

A FEW years ago we commented in these columns [1] on a paper by Dr. A. L. Wolbarst, of New York, in which he claimed to have proved that cancer of the penis never occurs in persons who have been circumcised in infancy. We then expressed a lingering doubt whether the statistical data on which the argument was based were sufficiently reliable. Since then Dr. M. Sorsby,[2] in his study on the incidence of cancer among Jews, has shown that Jews and Mohammedans enjoy complete freedom from cancer of the penis, and in this issue Dr. Wolbarst contributes further evidence which establishes this fact beyond doubt. He shows, moreover, that this freedom from cancer of the penis is due to the greater cleanliness made possible by circumcision. Circumcision is, therefore, to be recommended from many points of view as a measure of general hygiene. In civilised countries cancer of the penis is rare, while in the native races of the East who do not practise circumcision it is relatively common. In England and Wales, with an annual death-rate from cancer of about 26,000 men, only about 150, or 0·6 per cent., die from cancer of the penis. This difference is again due to greater cleanliness. Numerically, therefore, the general adoption of circumcision in this country would not materially diminish the general mortality from cancer. The great significance of these findings seems to us to lie rather in the demonstration of the fact that cancer is a preventable disease. For penile cancer the means of prevention are simple—namely, hygienic care by circumcision. But if hygienic care can prevent cancer in one organ why should it not do so also in other organs? For Jewish women observing the Mosaic code Dr. Sorsby demonstrat a lower incidence of cancer of the uterus as compa with Gentiles, and ascribed it to the insistence of t Mosaic code on sexual hygiene. Some years a Dr. T. H. C. Stevenson [3] showed that cancer of t upper alimentary tract, from the lips to and includi the stomach, is twice as common in the lowest soci classes as in the higher social classes, but no differen whatever was found between the two classes for t incidence of cancer in the lower alimentary trac from the stomach downwards. Quite recently D W. Cramer [4] has demonstrated from a compari of international statistics that cancer of the stoma is more than twice as frequent in a number of Cent European countries as it is in this country. Apparent there are groups of populations in Europe in which t incidence from cancer of the stomach is so high t of three people who die from cancer two die fr cancer of the stomach, while in this country on average out of four people who die from can only one dies from gastric cancer. Dr. Cramer arg from this that in those groups where the incide from gastric cancer is high, a large proportion of cases must be due to extraneous factors which avoidable. Evidence is therefore gradually accu lating which indicates that for a number of org cancer is, within limits, a disease which can prevented by paying attention to the general hyg of each particular organ throughout life.

DIGITALIS IN HEART DISEASE.

SINCE the nature of auricular fibrillation was ur stood it has been generally recognised that it this type of heart failure that digitalis has its gre effect. Some observers even consider that condition is the only true indication for dig therapy. Most cardiologists, however, are a that its administration is useful in congestive failure with normal rhythm, sometimes know right ventricular failure, although admitting th does not produce such consistently striking resu in auricular fibrillation. For some time now thes conditions have been generally regarded as the two types of heart disease in which the use of dig is desirable. It was therefore somewhat surprisi find White stating in his recent monograph [5] th considered efficient digitalisation and its mainter together with rest and restricted activity, o greatest value in abolishing attacks of cardiac as or in reducing their frequency. Harrison, Cal and Turley [6] have now investigated the effe digitalis in ambulatory patients, with little œdema, who suffered from attacks of cardiac as or from dyspnœa on slight exertion—so-calle ventricular failure. They found that in those paroxysmal nocturnal dyspnœa (cardiac as the administration of digitalis had a notably ficial effect. Of 19 treated, one was worse were much improved, while in the remaining 1 attacks were completely abolished, several having now been free from attacks for over two Thus this investigation fully corroborates W statement. As regards the patients with dyspn exertion the results of digitalis therapy were less remarkable, and were more difficult to quate treatment could be given; five showed a ial response at the clinic but have required almost inuous treatment with cortical hormone since harge; three showed an excellent response at the ic but did not continue treatment at home and l in crisis; nine did well at the clinic and have ained well since, with occasional courses of treatnt. The course of the disease is necessarily influed by the degree of the suprarenal damage, but s clearly established that the preparation is useful, l it is satisfactory to know that efforts are being de to prepare an active standardised preparation a commercial scale. Meanwhile it may be noted t S. W. Britton and his associates[2] at the Univery of Virginia, have found that in animals whose rarenal glands have been removed the extract is ective when given by mouth in three to five times intraperitoneal dosage. He thinks that with proved methods of preparation it is possible that al treatment may be of distinct service, and he edicts that suprarenal cortex will soon find wide plication in the medical field.

POLIOMYELITIS IN THE UNITED STATES.

THE serious epidemic of poliomyelitis in the nited States of America last year is reviewed in e November issue of the Statistical Bulletin of the etropolitan Life Insurance Company. Up to ct. 17th a total of 13,091 cases had been registered 19 States—a sickness-rate of 21 per hundred ousand of population. The highest rates were in onnecticut State 78·9, and Brooklyn City 94·5. It interesting to compare this epidemic with that of 916, when the total sickness-rate was 53·3, Brooklyn ity again leading with 224 per hundred thousand. he disease last year was therefore much less extenive than in 1916, and it was also much less virulent, he case-mortality being 10·3 per cent. as compared ith 26·2. The death-rate among children was no ess than 81 per cent. lower than that of 1916, and he incidence of crippling also was much less. A hart in the report shows the death-rate that might have been expected last year if calculated on the basis of policy-holders affected in 1916. The discrepancy between this curve and that of the actual death-rate is striking, but the two curves show a certain similarity in the way they rise from month to month. A careful comparative epidemiological study of these two outbreaks might provide valuable data.

BARBITURATES AS ANALGESICS IN LABOUR

THE latest candidates for use as analgesics in labour are the barbiturates, and the latest method of employing one of them, nembutal, is described by Dr. J. V. O'Sullivan and Dr. W. W. Craner on p. 119 of this issue. In the scheme they recommend barbiturate is combined with chloral, both drugs eing given by mouth, and it is of course a great vantage if the desired effect can be achieved by simple oral administration. Intravenous injection is bound to carry some added risk, though this may be very slight, and instances of thrombosis have been reported. Intravenous injection, moreover, could scarcely be entrusted to the midwife, whereas the authors of this new variation in the use of sedatives for labour think that their method may safely be conducted by her. In this we are not prepared at present to follow them, nor do we hold that the comparatively small number of cases in which the treatment has been tried provides a reliable basis for regarding it as free from all danger. Both the drugs used are potent, and it is plain that scrupulous care is necessary both in dosage and in determining the time for giving the additional doses. Nevertheless the results in the 60 cases on which the paper is based are excellent, and it is quite obvious that this use of nembutal and chloral in combination deserves an extended trial. If further experience substantiates the opinions of O'Sullivan and Craner we shall have an easily administered and very effective method which provides painless labour for a large proportion of cases with no untoward effect on mother or child. A recent paper[1] on pernocton in obstetrics supports the claims which German authorities have made for the use of this barbiturate in labour. Here, however, only the intravenous administration, supplemented by intramuscular injections, is employed, and the procedure comes therefore into rather a different category. Hitherto the chief objection to barbiturates in labour has been the frequency and sometimes the violence of the restlessness which may develop. In only two out of the 60 cases at the London Hospital was this symptom severe after the oral use of nembutal and chloral.

MEDICAL WORK IN BRITISH COLONIES.

THE Bureau of Hygiene and Tropical Diseases have issued, as a supplement to the *Tropical Diseases Bulletin* for December, 1931, a summary of the medical and sanitary reports furnished by British colonies, protectorates, and dependencies for the year 1929. This supplement, which will appear annually, is an innovation. The Colonial Office has hitherto published summaries of these reports, for official use only, under the title of Medical Research in the Colonies, Protectorates, and Mandated Territories. In this form appeared the reports for 1926, 1927, and 1928, edited by Dr. H. H. Scott as secretary of the Colonial Medical Research Committee. This committee no longer exists, and Dr. Scott has joined the staff of the Bureau. The wider publication of these summaries will be to the advantage of all concerned in the administration and growth of tropical medicine. Especially important matters of research are dealt with more fully in the *Tropical Diseases Bulletin* or the *Bulletin of Hygiene*. The supplement consists of a true record of hard routine work performed and a statement of the directions in which research is being carried out. Little attempt is made at comment, but the reader with knowledge and insight will grasp the continuous creative effort underlying these apparently dissociated accounts. For him this unassuming pamphlet describes one of the great endeavours of the human race. It is a pity that an account of public health work in the Anglo-Egyptian Sudan is not included for the sake of completeness, despite the fact that the Sudan does not fall politically within the scope of the collection.

WE regret to learn of the death on Wednesday last of Dr. James Calvert, consulting physician to St. Bartholomew's Hospital.

A HOSPITAL COLLECTORS' CLUB.—The Manchester Jewish Hospital has a club of young collectors of both sexes with a membership of 300 who, from first to last, have brought in some £12,000.

congress experts met to discuss how best to present the principles of industrial health and the methods for securing it, including the study of fatigue and its prevention, the influence of heat, of humidity, and of noise, and accidents caused by falls. Among official reports quoted upon work done and recent progress attained much space is deservedly devoted to the activities of the British factory inspectors. One notable article of special interest is entitled "Forty years of the Riving Knife," which knife is used with circular saws. The reader of this survey must be impressed with the more or less extensive campaign now conducted against factory accidents, as contrasted with the lack of attention paid to the personal factor in mining accidents, which are at least ten times as frequent; in accidents to seamen; in accidents occurring in quarries, in ship-building, in construction work, or among railway men. All of these have far higher rates and provide objectives urgently calling for more intensive attack.

INTELLIGENCE AND DISEASE.

DOES illness *in general* retard intellectual development or is it only certain diseases that have this effect, and what are they? Answers to these questions are sought in a report by Dr. Shepherd Dawson and Mr. J. C. M. Conn issued this week.[1] Binet intelligence tests, of which a short but admirable account is given, were applied to over a thousand children in the Royal Hospital for Sick Children, Glasgow. These children were drawn mainly from the lower end of the social scale and, judging by housing, occupation of parents, intelligence, or stature, they were below the general Glasgow average. It might be objected that a sick child is not a suitable subject for mental examination. This the authors do not believe, except, of course, when the patient is dangerously ill or delirious. The figures they produce certainly support them, for in intelligent quotient (or ratio, as the authors prefer to call it) the patients did not differ significantly from their healthy brothers and sisters. A comparison of the results obtained in acute, not-acute, and chronic patients, both among themselves and between them and their healthy brothers and sisters, with the results of tests made during and after illness, gives rise to the conclusion that, in general, sickness does not appear to retard mental development. In the acute stages of illness there is even a slight improvement in mental efficiency which, the authors suggest, may be due to a temporary increase in irritability of the central nervous system. There is no indication that chronic illness seriously retards the development of intelligence, as measured by these tests. On the other hand, although disease in general does not appear to produce any distinct effect on intelligence, there are some diseases in which changes can be clearly recognised. These were found to be mainly diseases of the ductless glands and of the brain. There was clear evidence of intellectual deterioration in most of the cases of post-encephalitis lethargica, though no statistically significant difference between those patients with the parkinsonian syndrome and those without it was apparent. The epileptic patients were on the whole of lower intelligence and when re-tested showed signs of deterioration. Eighteen cases of hysteria show a mean intelligence ratio only slightly below the average of the whole of the patients, while, contrary to beliefs sometimes advanced, there is no evidence th children suffering from chorea are drawn fro the more intelligent—the "highly strung, excitab nervous, bright, intelligent" type. There were l children with chorea and they proved to be neith brighter nor duller than the rest.

It has long been known that members of the upper social classes are on the whole taller than those of the lower classes. Even in the comparatively homogeneous social class here investigated this tendency is to be observed. When children of the same age are considered there is a tendency for the taller to be the more intelligent. This correlation, as the authors point out, raises some interesting questions. Are we to infer that superior intelligence is inherited with superior stature by certain stocks, or that superior stature in some way promotes the growth of superior intelligence, or that the more intelligent parents make better provision for the bodily growth of their children and that the cumulative effect of this is an increase in stature? It should be possible to test the last question by the examination of, say, a group of public school boys, where the "provision for bodily growth" would not differ appreciably.

SUPRARENAL CORTEX IN ADDISON'S DISEASE

THE paper from University College Hospital published on p. 125 of this issue will be valuable to all i this country who may wish to try treatment Addison's disease with suprarenal cortex. It is no nearly two years since W. W. Swingle and J. Pfiffner announced their success in preparing extract which would keep cats alive indefinite when the suprarenal glands were removed, and t latest report from them and their co-worker summarises the immediate results obtained in total of 20 human cases. In cats the dosage was 1 c.c of extract per day per kg. body-weight, and a corr sponding dose in man would be 60–90 c.cm. This cou not be provided from the limited supplies ava able for clinical use, but it must be remembered th in Addison's disease complete suprarenal insufficien is probably rare and substitution therapy has on to make up the difference between the output of t patient's own glands and his daily requirement. T largest single dose which has been given is 20 c.c intravenously, but 40 c.cm. has been given in one d in a crisis of the disease with no untoward effec For those patients who are so ill as to require co tinuous treatment 3 to 10 c.cm. has been the amou given daily. The immediate results are constant a striking. Improvement usually appears in 24- hours, and the maximal effect, as a rule, is not "over a period of from five to seven days af stopping treatment." Anorexia, nausea, vomitin and the distressing pain in the loins disappear a there is early increase in strength and enduran while decrease in pigmentation becomes appare within three or four days. Other benefits noted reappearance of appetite, gain in weight, return normal gastro-intestinal activity, and a sense of we being. When the patient is in a state of crisis shock at the beginning of treatment there is moderate increase of blood pressure, but little chan occurs when the initial condition is good. The resu in the 20 cases may be summarised as follows: case did not respond at all well to adequate tre ment and died; two were moribund and died befo ontreal. Out of several thousand deaths, there not a single case of penile cancer in a Jew. In large Jewish community of Palestine, Dr. H. sky, Acting Director of the Hadassah Medical nisation, reported [‖] that not a single case of le cancer was recorded in a Jew in a total of 21 new cases in the Skin and Venereal Clinic; case, however, was reported in a Christian Arab. rom these data it is evident that, while penile er may occur in an uncircumcised Jew, it does not r in Jews circumcised in infancy. The latter ervation has been made by competent observers, ong whom may be mentioned the following: J. Waring,[9] Da Costa,[10] Chetwood,[11] Watson and owsley and Kirwin,[15] Thomson [15] Eisendrath and Rolnick,[16] Legueu Michon,[39] and K. M. Walker.[41]

PENILE CANCER IN MUHAMMEDANS.

A high degree of immunity against penile cancer is o seen in Muhammedans, who, like the Jews, actice ritual circumcision. In India, Sutherland [17] orted 792 cancer cases, of which 72 were penile, occurring in Hindus (uncircumcised) and none in hammedans: while in a series of 64 cases seen in lcutta, and reported by Megaw [18] only two occurred Muhammedans.

Through personal correspondence I have been rtunate enough to obtain most valuable data ncerning penile cancer in Indian hospitals during e period 1925–1930. The figures are clearly shown the accompanying Table:—

Hospitals.	Total cancers in men.	Penile cancers.	Penile cancers in—		Percentage of Muhammedans in hospitals.
			Hindus.	Muhammedans.	
adras Presidency (a) and Madras City ..	5122	921	907	14	9·8
overnment of Bengal (b)..	1792	117	109	4	16·0
vil hospitals, Central Provinces (c) ..	460	113	109	2	21·8
vil hospitals, Assam (d) ..	318	49	44	4	37·13
Totals ..	7692	1200	1169	24	Average 21·19

(a) Personal communication, Surgeon-General's Office, Oct. 22nd, 1931.
(b) Personal communication, Surgeon-General's Office, July 23rd, 1931.
(c) Personal communication, Inspector-General's Office, June 30th, 1931.
(d) Personal communication, Inspector-General's Office, Sept. 18th, 1931.

If we combine these official figures with those of Sutherland and Megaw, we have a total of 8484 cancers in men. Of these, 1336 were penile cancers, of which 1303 occurred in Hindus (97·5 per cent.) and 26 in Muhammedans (2 per cent.), despite the fact that the average Muhammedan population in he hospitals reporting was 21·19 per cent. It is vious that if penile cancer occurred with equal quency in both these races, the number of cases reported in Muhammedans ought to approximate 254, instead of the 24 cases actually reported. (It may be noted, in passing, that the morbidity-rate for penile cancer in these Indian hospitals was 15·6 per cent., as compared with a rate of 2 to 3 per cent. in Europe and the United States. Vide infra.)

Sampoerno [19] investigated this subject among the Muhammedans of East Java, who also practice ritual circumcision. In a total of 78 cases of penile cancer, he reported seven in Javanese (presumably Muhammedans), three in Chinese, and one in a European, but he does not state definitely that the Javanese had been circumcised. It is possible, of course, as Kennaway points out,[20] that there may be a greater liability to penile cancer in Javanese than in other Muhammedan groups. As an instance of such racial peculiarity, Sampoerno asserts that cancer and ulcer of the stomach never occur among the Javanese.

Assuming that these seven Javanese were circumcised, we find that in the 1414 cases of penile cancer reported by these official and individual observers, only 33 (2·4 per cent.) occurred in circumcised men, as against 1374 (97·2 per cent.) in uncircumcised men living in the same communities. To these figures, if we add 1103 penile cancers reported in the United States, we have a grand total of 2484 penile cancers reported in uncircumcised men (Americans, Indians, and Javanese), as against 33 cases reported in circumcised men, all Muhammedans. Not a single case is reported in a circumcised Jew.

It is of some interest to inquire into the possible reason for the occurrence of penile cancer in Muhammedans, even to the slight extent of 2·4 per cent., as compared with the total immunity which characterises the Jews. The reason, I believe, is to be found in the fact that while ritual circumcision in Jews is performed on the eighth day of life, the Muhammedans perform their rite much later—between the fourth and ninth years. It is conceivable that in the presence of a foreskin, particularly if unretractible, there may occur the added chemical irritation due to retained secretions and the mechanical effects of dried smegma constantly eroding the delicate mucous surfaces. These irritating factors, acting for a period of four to nine years, may well be sufficient so to modify the character of the affected tissues as to constitute the necessary foundation for the later development of cancer, even though the offending prepuce had been removed at some time during youth.

This hypothesis is seemingly supported by recent reports in medical literature. R. O. Stein [21] discussing the occurrence of cancer on the inner surface of the prepuce in boys and young men with congenital phimosis, concluded that the malignancy arises from chronic irritation of the balanitic condition set up by the phimosis and that the precancerous stage can be recognised in the leukoplakic lesions usually observed in these cases. In three cases of penile cancer examined pathologically by Dormanns [22] in China, the men were 24, 26, and 34 years old respectively, and in all of them the cancer had developed on a greatly inflamed surface. Chavannaz and Magendie [23] report a case of a man of 31, treated in June, 1926, for phimosis and balanitis, who returned nine months later with an ulcerating cancer. One may safely surmise that while it is possible that the cancer in this case might have been prevented if circumcision had been done when the "balanitis" was under treatment, it is even more probable that the precancerous condition had already existed for some time and was erroneously diagnosed as "balanitis."

Further, it is generally known that penile cancer occasionally develops in men who were circumcised in adult life.[‡‡] "Many years may elapse," says Muhlpfordt [24] "before the precancerous condition

---

[‖] Personal communication, June 2nd, 1931.

[‡‡] In three of the series of 837 cases which I have collected, cancer had developed in men who had been circumcised in maturity. Inquiries made to determine when and why the operation had been performed failed to elicit this information.

SPECIAL ARTICLES

CIRCUMCISION AND PENILE CANCER.

By Abr. L. Wolbarst, M.D.,
of New York.

Commenting editorially on a previous contribution [1] to this subject, The Lancet said [2]:

> "*If Dr. Wolbarst is right in his conclusion as to the comparative freedom* [from penile cancer] *of the circumcised, his argument for universal circumcision is a strong one. If, on the other hand, he is misinformed about the rarity of penile cancer in Jews and Mohammedans it should be easy to prove him in error.*"

The main purpose of the present contribution is to clear up the doubt expressed in this editorial regarding the efficacy of circumcision in infancy as a prophylaxis against penile cancer.

Incidentally, the present study has provided the opportunity of arriving at a reasonably accurate estimate of the rate of incidence of penile cancer, as compared with cancer in men generally.

I confidently believe that the data herewith presented fully justify the following conclusions:

1. Cancer of the penis does not occur in Jews circumcised in infancy. There is no authentic case on record. It has occurred in an uncircumcised Jew.
2. Penile cancer does occur rarely in Muhammedans, who practise ritual circumcision between the fourth and ninth year, but not in infancy. A few cases have been recorded.
3. Penile cancer occurs almost exclusively in the uncircumcised, particularly in those with phimosis, and occasionally in men circumcised in adult life.
4. There is no racial immunity against penile cancer in Jews or Muhammedans. The one common factor which induces immunity is circumcision in early life.
5. Penile cancer constitutes at least 2 per cent. and possibly 3 per cent. of all cancer in men.
6. The annual mortality from penile cancer in the United States is about 225, all—or at least most—of which can be prevented by circumcision in early life.

The data upon which these conclusions are based were obtained through: (*a*) a questionnaire, (*b*) the medical literature, and (*c*) personal correspondence.* The questionnaire was regarded as the most effective method of obtaining the American morbidity-rate of penile cancer and its relation to circumcision, by interrogating a large number of hospitals throughout the country. From their replies it was hoped to obtain the morbidity-rate of penile cancer (for the period 1925–1930) as compared with cancer in men generally, and the rate of incidence, if any, in Jews, as bearing on the question of prophylaxis by circumcision in infancy. The questionnaire was sent to all skin and cancer hospitals, to all Jewish hospitals, and to 1250 of the largest general hospitals in the United States and Insular Possessions.† Replies were received from 421 hospitals representing every State in the Union,‡ as follows:

(*a*) 15 "general" hospitals reported that they do not accept cancer cases;

(*b*) 28 hospitals in 19 States reported no cancer cases of any kind in men;

(*c*) 43 hospitals in 21 States could not answer any of th questions submitted because of the manner in which th records are kept;

(*d*) 38 hospitals in 20 States reported no penile canc cases, but could not report their total number of canc cases in men;

(*e*) 92 hospitals in 31 States, with a daily average of 13,5 patients, reported 4607 cases of cancer in men without a single case of penile cancer;

(*f*) 26 Jewish hospitals in 11 States, with a daily avera of 4751 patients, 73 per cent. Jewish, reported seven cas of penile cancer, all in non-Jews. Fifteen of these institutions reported a total of 2166 cancer cases in men, while th remaining 11, including some of the largest and mo prominent, were unable to furnish this information becau of the manner in which their records are kept;

(*g*) 33 hospitals in 23 States, with a daily average o 8053 patients, 5·5 per cent. Jewish, reported 120 pen cancers, all in non-Jews. They were unable to report th total number of male cancer cases because of their record system;

(*h*) 146 hospitals in 37 States, with a daily average 32,656 patients, 3·4 per cent. Jewish, reported 710 pen cancers, all in non-Jews, in a total of 43,849 male canc cases—a penile cancer-rate of 1·62 per cent. in men.

Adding together the number of penile cancer cases i groups (*g*) and (*h*) we have a total of 830 cases of peni cancer, all in non-Jews, reported by 179 hospitals in States, having a daily average of 40,709 patients, of whic 4·4 per cent. are Jewish. To the above must be add seven cases of penile cancer (also in non-Jews) reported 26 Jewish hospitals, in which 73 per cent. of the patients a Jewish.

The grand total of penile cancer cases, therefore, is 83 reported by 205 hospitals in almost every State of Union, for the years 1925–1930.

It is of more than passing interest to note th one case of penile cancer in a Jew was reported by mid-West hospital, but this man had not be circumcised. This lends emphasis to the conclusi that the immunity of Jews to penile cancer is racial, but is due solely to the crucial fact th circumcision eliminates the major factor in development of penile cancer—namely, the prepu These data are fully supported by a survey of literature on the subject. A few instances suffice. In 1907, Barney [3] reported 100 cases penile cancer, all in non-Jews. More recent Dean [4] reported 75 cases, Schreiner [5] 60 cas Shivers [6] 5 cases, and Howze [7] 17 cases, all in n Jews. To these may be added nine cases seen myself (not published) also in non-Jews. In all these reports emphasis is laid on the presence phimosis as the predominant predisposing cau Howze furthermore urges circumcision at an ea age as a prophylactic measure. A review of th data reveals the striking fact that not a single case penile cancer in a circumcised Jew has been repor in a total of 1103 cases in the United States, desp the fact that Jews constitute about 3 per cent. the American population.

Sorsby [8] has shown that the incidence of can generally in Jews does not differ from that of n Jews. In England and Wales, he says, the mortal from penile cancer constitutes nearly 0·7 per ce of all male cancer deaths, and in Vienna ab 0·4 per cent. Nevertheless, Sorsby was unable find a single case of penile cancer recorded in 2 male cancer deaths investigated among the Jews London and Vienna. Furthermore, in an extens study of 40 cases of penile cancer made by Foder in 1926, none of the patients was a Jew, and in principal Jewish hospital in Vienna there had be no operation for penile cancer in 11 years.

A similar observation is made by F. L. Hoffma who made a *special* study of cancer among the Je rom these data it is fair to infer that there is irect relationship between the lack of hygienic of the male genitals and the occurrence of penile er, and that it is most common among peoples hom ignorance and poverty combine to maintain ital hygiene at its lowest standards.

---

* My thanks are particularly due to Dr. F. L. Hoffman, consulting statistician of the Prudential Life Insurance Co., and to Dr. Joseph Muir, medical director of the Radium Emanation Corporation, for their valuable contributions of statistical data.

† Only those "general hospitals" having 100 beds or more, as rated by the hospital number of the Journal of the American Medical Association, were addressed.

‡ As a matter of convenience, Alaska, the Philippines, Canal Zone, Hawaii, and Porto Rico are tabulated as individual States.

§ Personal communication, April 13th, 1931.

t is a curious fact that while all students of penile cer recognise the ætiological importance of mosis and uncleanliness and recommend circum- on only as a means of relief for the phimotic dition, most of them fail to recognise in early umcision a perfect prophylactic agent against mosis and its possible sequelæ. This attitude based on the fallacy that retractibility of the puce protects against the accumulation of patho- ic products in the preputial cavity, and therefore minates the foreskin as a potential factor in the usation of penile cancer. Lewis,[37] however, states at 19 of his cases had retractible foreskins without history of phimosis, five had acquired phimosis ring the growth of the tumour, and only nine gave history of long non-retractible foreskin; and he operly concludes that the retractibility of the epuce "is not insurance against retention of the egma."

It must be obvious to all who care to see that these nditions, arising basically in the unclean preputial vity, can be prevented by the simple medium of rcumcision in infancy, to say nothing of the many ther hygienic advantages of this procedure. Why ait until "balanitis" with its cancerous potentialities as supervened? It is a gratifying sign that the ractice of non-Jewish parents of having their male hildren circumcised early in life is rapidly growing n the United States, despite the myopic opposition f medical men who persist in regarding the foreskin s something holy and sacred. The active head of the most important anti-cancer organisation in this country writes me, "I don't think you have to plead cancer prophylaxis in justifying circumcision. Most of the children of my friends are circumcised early for general hygienic reasons." Circumcision of all male infants is therefore urged as a general hygienic measure and particularly, in this connexion, as an almost certain preventive measure against the later development of penile cancer.

SUMMARY.

(1) The morbidity-rate of penile cancer in the United States is at least 2 per cent. and possibly 3 per cent. of all cancer in the male; it is about 15 per cent. in the Far East. (2) Phimosis is universally recognised as the most important factor in the causation of penile cancer. (3) There is no record of a case of penile cancer in a circumcised Jew. (4) One case of penile cancer is reported (in this paper) in an uncircumcised Jew. (5) Two hundred and five American hospitals and six individual observers report 1103 cases of penile cancer in the United States, all in non-Jews. (6) Twenty-six Jewish hospitals (included n the above) do not report a single case of penile ancer in a Jew. (7) Penile cancer occurs rather rarely (2·4 per cent.) *in Muhammedans; in India and* Java, 33 cases of penile cancer were reported in (circumcised) Muhammedans, as against 1381 in uncircumcised men living in the same communities. If we add 1103 penile cancers reported in the United States, we have a grand total of 2484 penile cancers reported in uncircumcised men (Americans, Indians, and Javanese), and 33 in circumcised men, all Muhammedans. Not a single case is reported occurring in a circumcised Jew. (8) There is no racial immunity against penile cancer in Jews and Muhammedans. The immunity is provided by the practice of circumcision in early life. (9) Leukoplakic conditions leading eventually to cancer may be observed in boys and young men. Years may elapse before the conditions are recognised as frankly malignant. (10) Circumcision in adult life or adolescence does not protect fully against future malignancy because of the tissue damage already effected. (11) "Chronic balanitis" in the middle-aged or elderly should always be regarded as potentially malignant. (12) At least 225 deaths annually in the United States, and 150 in England and Wales, and probably twice as many non-fatal cases can be prevented by the circumcision of all male children in infancy.

SWINDON ISOLATION HOSPITAL.—The mayor of Swindon, Alderman J. L. Calderwood, last week opened a new administrative block this hospital, providing 33 bedrooms and 15 bathrooms.

OTLEY DERBY CLUB.—It is proposed to continue and extend the operations of this club, which was formed in the early part of last year. The annual subscription was fixed at 10*s.*: it was provided that 20 per cent. of the receipts should be given to hospitals, and that the remainder of the money would be given in prizes upon the result of the Derby. The membership reached nearly 45,000 and £4500 was distributed among British Hospitals. The first prize-winner in the Derby event received £5000, the second £2500, and the third £1000. The balance was devoted to the purchase of the club premises and the cost of maintenance.

passes over into a clinically and histologically recognisable malignant tumour." In 3 per cent. of Dean's cases,[4] leukoplakia unquestionably preceded the cancer, but all of these patients had been circumcised in adult life, "probably for sufficient cause." It is reasonable to assume that the leukoplakia, admittedly present, was the most probable cause. In Schreiner's series of 60 cases,[5] eight gave a history of circumcision before the beginning of the disease, and in one case the *epithelioma appeared one year after the circumcision.* He does not state why the operation was performed, but there is usually a good reason. Lloyd Lewis,[37] in a report of 70 cases of epithelioma of the penis (Brady Urologic Clinic, Johns Hopkins Hospital),§§ referring to several cases in his series, says, "it is entirely possible that both of these patients had early malignancy at the time of their circumcision."

In these and other cases with a similar history the explanation is probably the same. The foundation for the cancer was laid during the years of irritation provoked by the abnormal conditions within the preputial cavity, and the fundamental trauma of the tissues had already been permanently effected when the circumcision was done. The fact that the circumcision scar is often the seat of the cancer lends further support to this view, inasmuch as cancer does not occur in the scar of Jews circumcised in infancy and but rarely in Muhammedans.

The conclusion is inescapable that the irritation in the preputial cavity may begin in early life and that the tissue damage thus produced may persist as a foundation for cancer long after circumcision has been performed. All of which gives point to the conclusion that the earlier in life circumcision is done the less danger there is of the development of *cancer in later life. The maximum degree of protection* is provided by circumcision in infancy, as exemplified in the 100 per cent. immunity enjoyed by the Jewish race. In other words, where there is no foreskin there will probably be no cancer.

That this immunity is not racial, as Young[25] and others believe, is made evident by the occurrence of penile cancer in the case of the uncircumcised Jew already referred to, and by the almost complete immunity enjoyed by Muhammedans of non-Semitic origin. Commenting on this aspect of the subject, Sorsby[8] emphasises the fact that the Indian Muhammedans are not allied to the Jews racially, as the Arabians are, and that the one common factor shared by Jews and Muhammedans in this respect is the "habit of circumcision." In short, penile cancer is absent, not in races, but in those communities in which circumcision is practised as a ritual. It is the absence of a prepuce from the earliest days of life that provides the immunity against cancer.

MORBIDITY-RATE OF PENILE CANCER.

We have seen that the questionnaire elicited complete responses from 146 hospitals, in 37 States, having a daily average of 32,656 patients. These institutions reported a total of 43,849 cancers in men, of which 710 were penile—a rate of 1·62 per cent. But *this cannot be accepted as the final morbidity*-rate for penile cancer; other factors must be taken into consideration. First is the fact that cancer is not a notifiable disease, and it is quite certain that a considerable number of penile cancers, not fatal and therefore not in the vital statistics, are "covered up" for social and family reasons and thus remain unrecorded. Again, all penile cancer cases do not go to hospitals for treatment. Many cases are successfully treated by irradiation and X r
at doctors' offices and out-patient clinics. Th
there are the cases in which the growth rema
undiscovered for many months, death occurri
because of some accident or intercurrent dise
E. Langer[26] reported the case of a man of 68 who h
phimosis. On making a dorsal incision, he fou
a flat ulcerating squamous-called carcinoma und
the foreskin. There must be many such case
I have encountered two myself. In one, the m
had been treated during nine months for balanit
and the epithelioma was discovered only when t
prepuce was slit open; in the other case, five mont
had elapsed before the diagnosis was made by dor
incision.

In view of these circumstances, taking as a b
the 1·62 percentage in the 146 hospitals referred
it is a conservative estimate that the morbidity-
of penile cancer is at least 2 per cent. and poss
3 per cent. of all cancers in men. This esti
is approximately one-half that of the famous surge
Winiwarter,[27] 2·55 per cent., and Billroth,[28] 3·10
cent., of all cancers in both sexes. Englisch,[42] i
extensive study of the literature, concluded that
morbidity-rate of penile cancer was 1·78 per c
as compared with cancer in men generally, and
per cent., compared with cancer in both sexes.

MORTALITY-RATE.

While this paper is not concerned with
mortality-rate, it is pertinent to consider it b
as an indication of the seriousness of penile c
as a cause of death and its relative frequen
various localities. According to the United
Census Bureau, there were 144,206 deaths i
United States from cancer in males in 1927, 192
1929. Of these, 654 were penile, a rate of 0·
cent. In England and Wales[29] in the same
the rate was 0·61 per cent. In the hospitals
U.S. Veterans' Bureau, P. B. Matz[38] reported
deaths from penile cancer in the fiscal years 19
Of these, two were in the age-group 30–39 an
in the age-group 40–49. The total number of

§§ These cases are included in the series of 837 cases which have collected.

‖‖ Personal communication, Oct. 22nd, 1931.

al weekly and monthly working hours. In the e mills, for instance, in July, 1929, the working urs were increased from 54 to 60 per week, the ger hours resulting in increased earnings. In July, 30, they reverted to the 54-hour week, and in lition closed down completely for one week in each nth; but compensation was given for the shorter ek in the form of an increase in wage rates, and a osistence allowance was paid during the week of eness. Some decrease in the average monthly rnings was inevitable, but owing to these measures was only slight. Considering the circumstances, tal emoluments seem to have been maintained rprisingly well.

The architectural features of many considerable ctories still leave much to be desired, and, owing primitive conditions, it is not always possible to force the regulations rigidly. One case is quoted here immediate enforcement would have thrown 00 people out of work, but a remedy was eventually und during a change-over to electric power. The remises of half the registered printing presses are rdinary dwelling-houses, and are not as a rule atisfactorily lighted or ventilated. Trouble arises in uch cases from injurious gases, and lead poisoning is serious problem. Many orders were issued during he year to printing presses, but it is evidently very ifficult to get reasonable precautions against lead oisoning carried out. Washing can usually be rranged for, but even in the larger presses food precautions are a difficulty, owing to the impossibility of getting people of different races and castes to eat together. It is a common practice for employees to bring their dinner with them, and keep the food beside them while at work. This difficulty has been met in a large railway press by having three separate mess-rooms for Hindus, Mohammedans, and Anglo-Indians, but it is obviously impossible for the smaller establishments to make such arrangements. The report states that the prevalence of lead poisoning, even in registered printing presses, cannot be denied, while investigation of the appalling conditions in some of the unregistered presses suggests that it must be much more prevalent in them.

The result of a general survey of the housing conditions of the larger factories is distinctly encouraging. In spite of lean years considerable advance is being made in Calcutta, as in Bombay, where a large amount of excellent accommodation is available in great blocks of flats, the chief difficulty being to induce the workers to leave their slum dwellings to inhabit them. But, with the exception of tea factories, in the smaller concerns employees usually have to fend for themselves, usually in mean and congested areas. In tea factories, labour recruited from jungle areas in the north often prefers flimsy bamboo huts, thatched with grass, to more permanent dwellings, one reason being the superstitious custom of firing a hut after a death in it, to drive away evil pirits.

The average number of women employed during the year in registered factories was 73,951, as against 77,966 in 1929, and of children 16,630, as against 23,036. The general tendency in jute mills is to eliminate children, and out of 91 mills 45 have dispensed with child labour entirely, despite the fact that children, on account of their height, are better fitted than adults for the shifting work on spinning frames. Generally speaking, it appears that the conditions of employment of both women and children are improving, and both the Government inspectors and the Society for the Protection of Children are evidently on the alert to discover cases of abuse. Only children of 12 years or more are eligible for employment in factories.

The report is not optimistic about sanitary arrangements. In the larger factories hygienic conditions have made moderate progress, but in the smaller little improvement is manifest. Even where good latrine accommodation is provided it is often abused. In the smaller factories conditions are commonly abominable, and repeated prosecutions seem to have little effect. Some advance is being made in the installation of septic tanks, and the Willas aerobic septic tank is mentioned favourably. One difficulty is the uncleanly habits of the mill hands, who frequently use surface drains for latrine purposes, thus fouling the effluent. Complaint is made of the fouling of the Hooghly river, which furnishes part of the water-supply of Calcutta, in this way. It is suggested that legislation should be provided which would give no option to the intending employer of a certain number of workers but to erect a septic tank latrine.

Ventilation also is the despair of the factory inspector, owing to the unsuitable premises in which many of the smaller firms carry on their work, but special attention is being paid to manufacturing processes in which dust and fumes are generated. A dry-battery factory and an electric steel foundry are cited as instances in which orders were issued for the installation of extractor fans in large establishments, but in the smaller factories the cost of such a system would be prohibitive. It is surprising to read that tea factories are amongst the worst offenders for the generation of dust. The present depression of the industry is an obstacle to progress in the way of fitting efficient trunk systems for the removal of tea fluff.

Apart from a severe epidemic of malaria in the Calcutta area the general health of operatives was normal. Maternity benefit schemes have been very successful, and are greatly appreciated by the workers. An important development which is attributed to the Whitley Commission was the decision of the Indian Jute Mills Association to establish welfare centres, baby clinics, and creches in all mills within their membership.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdr. H. H. Ormsby is placed on the retd. list.

Surg.-Comdr. C. J. Aveling is placed on the retd. list with the rank of Surg. Capt.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt.-Comdr. R. H. O. B. Robinson is placed on the retd. list at his own request.

ROYAL ARMY MEDICAL CORPS.

Maj. (temp. Lt.-Col.) J. C. L. Hingston to be Lt.-Col.

Maj. A. E. B. Jones to be temp. Lt.-Col.

Capt. F. V. Cant relinquishes his temp. commn. and retains the rank of Capt.

TERRITORIAL ARMY.

Lt. E. T. Colville, from Active List, to be Lt.

INDIAN MEDICAL SERVICE.

Lt.-Col. L. Cook to be Col.

ROYAL AIR FORCE.

Group Capt. H. Cooper, Honorary Surgeon to The King, is placed on the retd. list.

COLONIAL SERVICE.

Dr. N. J. Abbensetts has been appointed M.O., Boundary Commission, British Guiana; Dr. L. R. Levy, M.O., Jamaica; and Dr. D. C. Ogilvie, M.O., Leeward Islands.

MEDICINE AND THE LAW.

Escape of Child from Institution.

ACTS of Parliament are ineffective if they march ahead of public opinion. In particular, measures of social reform which involve official interference with family life encounter a resistance from parents which magisterial authority (reflecting public opinion in some degree) seems disinclined to quell. Prosecutions under Section 12 of the Children Act, where a parent refuses to allow a child to undergo some necessary and proper surgical operation, are not unfamiliar; the magistrates realise that the parents' feelings are natural if mistaken and, as a rule, they explore any expedient sooner than impose a penalty. A similar tendency appears in recent proceedings under Section 53 of the Mental Deficiency Act against a mother for assisting her daughter to escape from an institution. There was a summons also against the father for secreting his daughter. For the London County Council it was explained that the child had attended various mental deficiency schools and in April last was recommended for treatment at an institution in Hampshire. Last September she was allowed out with her mother on the understanding that she would return the same evening. She did not return and eventually was found at her parents' house in Islington. The father told the local authority's officer that the girl was in a good situation and had a good home. He refused information and invited prosecution; "I will go to prison," he said, "it is a shame she is not to be allowed out." When the case came before the Clerkenwell police-court, the magistrate invited the legal representatives on both sides to confer. As a result the L.C.C. representative said that, if the child was allowed to go back to the Hampshire home, he would do all in his power to facilitate action by the parents to have the order set aside; the parents' representative assented to this compromise. The metropolitan police-court bench is to-day unusually rich in able and experienced magistrates. They use their discretion to the great advantage of us all. But such reluctance to enforce the law teaches the social reformer the lesson that there are limits to what can be achieved by mere Act of Parliament.

Dangerous Drugs Act: Charge against Medical Attendant.

George Edward Williams, described as a medical attendant, was charged at Marlborough-street police-court a fortnight ago with being in unauthorised possession of morphine sulphate and cocaine hydrochloride contrary to the Dangerous Drugs (Consolidation) Regulations of 1928. A representative of the Director of Public Prosecutions outlined the case against him. It was alleged that Williams was acquainted with a Dr. Kirton, who formerly had a surgery at Foley-street, and that, when Dr. Kirton left, Williams took a lease of the premises and practised there as a doctor. Chemists gave evidence that they had supplied drugs to him in the belief that he was a registered medical practitioner. It is alleged that in one case he actually prescribed a dangerous drug.

On remand last week it was stated that a further charge of forgery is likely to be preferred. The case was adjourned pending the completion of inquiries.

THE LÜBECK TRIAL.

(FROM OUR BERLIN CORRESPONDENT.)

(*Continued from p. 102.*)

IT was expected that the hearing of witnesses and of medical experts would end on Jan. 11th, and tha after an interval of three days the public prosecutor, counsel for parents, and counsel for the accused medical men and nurse will plead. The verdict wil thus probably not be pronounced before Jan. 20th This long trial will thus finally be closed after a duration of about three months.

In the course of the trial the question was discussed whether the disaster could have been avoided if the physicians had not assumed that the infant G., the first victim, had suffered from congenital tuberculos Prof. Schürmann, of Berlin, gave evidence that aft the administration of the vaccine swelling of th cervical glands had developed. In congenital tuber culosis an isolated swelling of the cervical glands without other symptoms, seldom occurred. Th infant G., having been the first who showed suc symptoms after the administration of the B C G, i would have been better to consider the possibilit that the disease had been caused by that administra tion. If the attending physician had known that i the laboratory the B C G was cultivated together wi virulent tubercle bacilli he would certainly have h that suspicion. Unfortunately there was only litt collaboration between the physician of the childre hospital, Prof. Klotz, and the head of the laborator Prof. Deycke. Prof. Deycke's duty as a bacteriolog would have been to stop the distribution of the tu as soon as he was informed that an infant had beco ill, until he had tested in animals the condition the emulsions. Prof. Klotz replied that he had reas to believe that the infant G. suffered from congen tuberculosis, because the mother was tuberculo When the glandular swelling extended he had remov a piece of a gland for bacteriological examination, ascertain whether B C G or human bacilli were pres The examination of the gland had convinced him t the case was one of congenital tuberculosis. He still of that opinion, because tuberculosis could be acquired so soon after the administration of B C G. In fact, the other infants became ill several weeks afterwards. He had not been infor that in Lubeck not only infants from tubercu families, but all the new-born children were to treated with the B C G.

INDUSTRIALISM IN INDIA.

A REPORT FROM BENGAL.

A SAMPLE of Indian industrial conditions is provi by the annual report for 1930 on the administra of the Indian Factories Act in Bengal. The num of registered factories had increased from 148 1555 since the previous year but of these 111 did work at all, this number including 44 rice mills, 1 mills, 14 general engineering workshops, and 11 presses. The number of operatives was 441,51 against 466,741 in the previous year, and even in there had been changes in the general condition workers and their wages as a result of the indus depression. Many mills had to revert to the si shift, and various modifications were made in

CORRESPONDENCE

POINTS IN THE NOTIFICATION OF INDUSTRIAL DISEASES.

To the Editor of THE LANCET.

R,—Many medical men are, I am afraid, unaware ieir statutory obligation to notify certain industrial ases. I may quote two recent examples in regard -oxic jaundice, one a series of cases due to tetra-rethane, and the other a series due to arseniuretted rogen. Only one of the cases was notified by a lical practitioner. In regard to the series due to niuretted hydrogen, notification of the earliest would have led to the adoption of measures ch might, it is anticipated, have prevented the urrence of subsequent cases, including two deaths. s serious result alone seems to be ample justification asking you to allow me to draw the attention the profession to the very important statutory uirement of notification of industrial poisoning ler the Factory and Workshop Acts, 1901–1920, 1 Lead Paint (Protection Against Poisoning) Act, 26.

Every medical practitioner attending on, or called to visit, a patient whom he believes to be suffering m any of the following :—

Lead poisoning,
Phosphorus poisoning,
Arsenical poisoning.
Mercurial poisoning,
Carbon bisulphide poisoning,
Aniline poisoning,
Chronic benzene poisoning.
Anthrax,
Toxic jaundice,
Epitheliomatous ulceration or
Chrome ulceration,

contracted in any factory or workshop,

required by Section 73 of the Factory and Workshop ct, 1901, under penalty, to notify the case forthwith the Chief Inspector of Factories. Home Office, ondon, S.W.1, and by Section 3 of the Lead Paint rotection Against Poisoning) Act, 1926. he is also quired to notify lead.poisoning contracted by any rson employed in, or in connexion with, the painting any building whether or not that building is a factory workshop, unless it has already been so notified ; ıd he is entitled to a fee of *2s. 6d.* for so doing.

Forms for notification will be supplied on application to the Chief Inspector of Factories, Home Office, ondon, S.W. 1.—I am, Sir. yours faithfully,

JOHN C. BRIDGE,
H.M. Senior Medical Inspector of Factories.
Factory Department, Home Office, Whitehall, S.W.,
Jan. 11th, 1932.

MULTIPLE PRIMARY CARCINOMA IN THE BUCCAL CAVITY.

To the Editor of THE LANCET.

IR,—The case recorded by Lord Moynihan in hich carcinoma developed at intervals in different arts of the buccal cavity is to some extent paralleled three cases recently under treatment at the Cancer ospital, and it may be that added interest attaches, that radium was used to treat the initial lesion.

In all three cases the patients were elderly males, nd the initial lesion "epithelioma" was in the nterior part of the floor of the mouth. In all three ases sound healing occurred without any sign of cal recurrence, and there was no connexion clinically etween the initial lesion and the growth that followed.

In one case the second growth involved the soft palate and fauces, and was noticed two years after the initial lesion had been treated. In the second case a mass of glands developed a year after treatment, and examination showed an ulcerated area in the pyriform fossa on the same side. In the third case, death from carcinoma of the pharynx and breaking down glands occurred 17 months after treatment to the floor of the mouth.

Every surgeon with experience of excision operations on the tongue will endorse Lord Moynihan's contention as to the rarity of local recurrence thereafter. Attached to the Cancer Hospital for 20 years as surgical registrar and surgeon, I have not met with such a happening. The fallacy instanced is one that has been quoted to me several times recently by candidates for higher surgical qualifications.

Radium for the last few years has to a large extent displaced surgery in the treatment of carcinoma of the tongue, and it may be that this myth as to local recurrence after surgical removal owes its origin and growing currency to those rising radiologists and surgeons whose clinical experience has been confined to this period.

This question of recurrence is surely fundamental if any attempt is to be made to assess the relative value of different methods of treatment, and it is of importance therefore that inaccuracy should be corrected.—I am, Sir, yours faithfully,

PERCIVAL P. COLE.
Wimpole-street, W., Jan. 11th, 1932.

A NEW METHOD OF APPROACH TO THE SEMILUNAR CARTILAGES OF THE KNEE-JOINT.

To the Editor of THE LANCET.

SIR,—I fear that Mr. Harry Platt has misinterpreted the purport of my Clinical Note with the above title (THE LANCET, Dec. 26th, 1931). I have made no claim there or elsewhere to be the originator of the "combined anterior and posterior approach to the semilunar cartilage," although I first performed the operation in 1924, before, as far as I am aware, any reference had been made to this method in surgical literature. It certainly appears that to the late Mr. Alwyn Smith is due the credit of first publishing the "combined anterior and posterior approach" (*Journal of Bone and Joint Surgery*, April, 1925). Whatever claim to originality my method possesses lies in the particular mode of combined approach advocated, which, from an experience of eight years. I believe to possess special advantages. On referring to the late Mr. Alwyn Smith's method of approach. I find certain fundamental differences between his method and mine, which must be immediately obvious to anyone who compares the two methods and accompanying diagrams. For instance, Mr. Alwyn Smith advocated *two separate incisions*, the posterior of which is *vertical ;* and his method of opening the posterior part of the joint capsule differs from mine. Also in my method, the semicircular flap permits the internal lateral ligament to be freely exposed and this structure acts throughout the delicate operation as an exceedingly helpful surgical landmark. When Mr. Platt states that the procedure described by me is "familiar to most orthopædic surgeons in this country," I presume that he is referring in a *general*

PANEL AND CONTRACT PRACTICE

Health Insurance Certification: Complaints of Misleading Statements.

THE East Sussex Insurance Committee has had occasion to complain of misleading certificates being issued by three practitioners. After examination of the circumstances and after taking into account the doctor's explanations, the committee has recommended the Minister of Health to withhold the sums of ten, five, and seven guineas respectively from the remuneration payable.

In the first of the three cases the patient was an elderly woman suffering from advanced rheumatoid arthritis and unable to move about her room unaided. In a series of monthly certificates, giving the cause of incapacity as rheumatoid arthritis, the practitioner stated that he had examined the patient on the dates named. The certificates were dated in Nov. and Dec., 1930, and in the first five months of 1931. Some time after the latest of them the patient signed a statement that the practitioner last called to see her about six months ago. When the question was taken up last June, the practitioner admitted he had not visited or seen her between November, 1930, and June, 1931. Before signing the certificates, however, he had satisfied himself that there was no change in her condition by inquiry of the Queen's Nurses who reported to him weekly. He practised in the town in which the patient lived, and at no great distance from her home. The Medical Service Subcommittee's comment was that the practitioner did not frankly admit his fault but seemed to harbour the idea that his error was merely technical and that he could throw some of the responsibility upon the Queen's Nurses. The subcommittee pointed out that no practitioner can delegate his responsibility for issuing certificates of incapacity; certification is not a mere technical matter nor does it fall within the category of merely clerical work. "It is essential," they observe, "that medical men should realise that certification for National Health Insurance purposes is an essential part of their duty. The obligation to visit once a month a patient who was practically bedridden cannot, in the subcommittee's view, be considered unduly onerous."

The second case was that of a practitioner who gave a monthly certificate in each of the first five months of 1931 for a patient 57 years of age suffering from carcinoma of the stomach. Each certificate stated that the practitioner had examined the patient on the date named; the cause of incapacity was given as "gastric neoplasm" or "abdominal neoplasm." Last June the patient signed a statement that the practitioner had not visited him since the previous December, though passing his door twice a week. The patient was able to go for walks and could easily have visited the surgery. He did not visit the surgery, nor did the doctor visit him, during the period covered by the certificates; but it did appear that the doctor had seen him walking about the village at about the dates of the certificates. The certificates were given to the patient's wife who called at the surgery for them. The patient lived in a small village some miles from the doctor's house; but the doctor had a surgery in the village within fifty yards of the patient's house; the doctor attended this surgery on Thursdays; all the certificates were dated on Thursdays. The subcommittee conceded that the practitioner was under no obligation to call on the patient; it was for the patient to present himself at the surgery. The patient had at times suffered from mental aberration and there was perhaps a doubt of the effect which a visit to the surgery might have had on his mental condition. As already stated, this practitioner did see his patient but not in the professional sense. The subcommittee considered that, while an exhaustive physical examination may not be necessary on every occasion when a certificate is issued, the practitioner must see the patient in a professional capacity, and take proper steps to confirm his expectation, based on previous knowledge, that the patient remains incapable of work.

In the third case it was again the fact that the patient had the obligation to call at the practitioner's surgery rather than that the doctor had to visit the patient. In both the second and third cases the doctor seems to have erred out of good nature, giving certificates to the patient's wife to avoid giving trouble. In the third case the patient was aged 58, and suffered from rupture, piles, epileptic fits at rare intervals and other ailments, definitely making him quite unfit for work; he had been receiving benefit since the beginning of 1927. The practitioner gave him eleven certificates between Oct. 8th, 1930, and the end of July, 1931; the first five indicated the cause of incapacity as "Con. after pneumonia," the last six, "Con. after pneumonia; epilepsy." In each certificate the practitioner stated that he ha examined the patient on the date named. Las August the patient signed a statement that it wa fifteen months, as far as he could remember, sinc the doctor came to the house to see him. The patier was quite able to walk to the doctor's place of ca in his village but did not do so. At an earli period the patient had come in person for his certi cates; during the time of the eleven certificat he had sent his wife for them; after the questic had been raised, the practitioner insisted on tl *plaintiff coming personally* for his certificates.

The subcommittee expressed appreciation of t frankness with which the second and third prac tioner admitted carelessness. The period of irregul certification was twice as long in the third case as the second. Such considerations explain the diff ence in the sums recommended to be withheld in t three cases. In all three cases there were cert mitigating elements. The subcommittee could dr attention to the fact that in each case there w chronic disease and undoubted incapacity, th monthly certificates were justifiable, that acti treatment would have produced little or no rel or improvement and that, in consequence of t foregoing elements in each case, the approved soci was not prejudiced by paying out benefit not prope due. It is nevertheless impossible to resist t Insurance Committee's conclusion that the certifica contained false and misleading statements, or challenge its conclusion that the issue of su certificates deserves grave censure.

BIRMINGHAM HOSPITAL SUNDAY FUND.—At t annual meeting of this fund last week it was sta that since 1859 a total of £103,541 had been collected, average, after deducting a fraction over 6 per cent. for expenses of administration, of £4953 a year. The collecti in 1931 fell below the figure of the previous year by nea £500. There has, indeed, been a steady decrease for sc years past, which is attributed to the university studer carnival being held on the day before Hospital Sunday.

›ut of print for very nearly 20 years, though ıerished possession of all who wish to obtain ;ve information on clinical signs, symptoms, ›ntial diagnosis. It is only natural that se works are out of date when considered ›resent-day point of view, yet there is ;le word which those who love these works ɔ see cut out in a new edition—one would ːem added to, but not cut down.

ıg time since anything of so great an English medical literature has appeared on, but last week's LANCET gave a ɔrk by one who may be a newcomer to 'ish classics. Dr. Needham's "Chemical [1] in three volumes has been produced ›sire to present a complete account of the English language, and that he has can be no doubt. His book, like a ıd, presents many facets; it possesses ıarm and distinction, great learning, ːal material and, at the same time, etailed biochemical material. It is a biochemist writing on embryology. s, both gross and microscopical, will see what they must have considered mpart broken down and crossed by an invading horde of, to their mind, can imagine His and Von Graefe graves at the thought of embryology the hands of the morphologist into ochemist. The younger generation has ent of the cutter of sections and the of embryos. Admittedly, these workers s of their labours may be able to explain rare congenital cardiac malformation but in the dealing with this they have, of the slightest interest except to obtain nicely useum specimens; or, on the other hand, rches enable a physician to give a clinical the embryological basis of cleft palate and All these vaunted advantages for the knowembryology can only strike the practical ːist as belonging to the irritating phenomena wise after the event. Dr. Needham's work ıg a great flood of enthusiasm into the study ·ology from an entirely new aspect. This heartily recommended to all professors of who torture their students with details ıg the closure of the pleuro-peritoneal , since here they will find a constructive and ve science as compared with one of almost gical interest.

I am, Sir, yours faithfully,

th, 1932. DODDERER.

ENTIVE MEDICINE IN ITS RELATION TO AVIATION.

To the Editor of THE LANCET.

May I be permitted to call attention to a ıt liable to misinterpretation in my article subject in your last issue? In a sentence ng the disposal of excreta (p. 112) I do not imply that the Air Ministry regulations he dropping of excreta from the air. On the , they forbid it.

I am, Sir, yours faithfully,

E. GOODWIN RAWLINSON, M.D.

-square, W.C., Jan. 9th, 1932.

[1] ical Embryology. By Joseph Needham, M.A., Ph.D. e. At the University Press. 1931.

A SOURCE OF ERROR IN MEASUREMENTS OF URINE SECRETION.

To the Editor of THE LANCET.

SIR,—Drs. Kerridge and Ellis (THE LANCET, Jan. 9th, 1932, p. 83) have fortified the old-fashioned obstinacy of those of us who have long felt examination of the "twenty-four hour specimen" of urine to be a better clinical guide than any *ad hoc* "renal efficiency" test. But surely they are in error in suggesting that in "the prone position" micturition incompletely empties the bladder. Usually, of course, micturition in bed takes place in the *supine* position.

I am, Sir, yours faithfully,

Jan. 8th, 1932. CAVILLATOR.

OBITUARY

TOM BIRD, M.R.C.S., M.A. Oxf.

WE regret to announce the death, which occurred on Jan. 3rd at his residence at St. Margaret's-on-Thames, of Mr. Tom Bird, consulting anæsthetist to Guy's Hospital and the East London Hospital for Women.

Mr. Tom Bird, who was born in 1844, was educated privately, and entered Oriel College, Oxford, in 1862. He graduated in Arts but never joined the medical school, proceeding to Guy's Hospital, and taking the diploma of M.R.C.S. in 1869, at which date, and for long after, the single qualification was sufficient for the purpose of registration. He entered general practice, but being appointed anæsthetist to his old hospital he gradually became a specialist along this line, lecturing in the medical school and instructing the students at Guy's in his subject. He later became also anæsthetist to the Dental Hospital of London, the Hospital for Women in Soho-square, and the East London Hospital for Women, and obtained wide professional popularity as an administrator.

We owe to the courtesy of Mr. C. H. Golding Bird (not, by the way, a relative) the following note on Mr. Tom Bird as a professional colleague:—

"The recollection of Mr. Tom Bird as an anæsthetist, that I retain, has always been a pleasant one, for both privately and professionally he was a gentleman of unfailing courtesy. Quiet, refined—one may add dignified—in his manner, he at once impressed his patient with confidence, whilst the surgeon with whom he worked always felt that in his hands there was no undue anxiety in regard to his patient. His were the days of chloroform, ether, and A.C.E., and none of the present-day drugs of refinement in anæsthetics, or complicated appliances, were in use, so that, if possible, more care in the administration of the anæsthetic was then required of the administrator than at present. Tom Bird never took risks, and always warned the operator if he felt that the border-line of safety was being neared; on the other hand, he was by no means an over-anxious or hesitating administrator. He was much valued at Guy's as a teacher; he impressed his pupils by his manner, and never spared trouble in explanation and demonstration, always, however, exacting from them the closest attention to every detail. He was therefore much valued on the teaching staff, and nothing but the lapse of years caused his resignation, a matter of great regret both to his colleagues and the students he so well instructed."

A correspondent, a personal friend of Mr. Tom Bird, writes: "A few remarks on Tom Bird may be

LOSS OF MEMORY.

To the Editor of THE LANCET.

SIR,—Almost every day one meets in the lay press accounts of the disappearance of individuals, generally of the male sex, accompanied by the statement that such individuals are believed to be suffering from loss of memory. In your issue of Jan. 2nd a most detailed account of a genuine case of such a condition, with its treatment and outcome, is described. It is interesting to note that in this particular case the police were at first extremely sceptical, and regarded the condition as pure malingering. In this opinion they were doubtless influenced by the fact that within the previous five years one of the authors in the present case had been consulted on three occasions by them in cases of supposed loss of memory, all of which had turned out to be simulation.

That genuine cases of loss of memory do occur is patent, but would appear to be extremely rare. The matter is one of marked medico-legal importance, and it would be of great interest to hear of the experiences of other practitioners with this type of case. It is only on such evidence that an estimate of the true prevalence of genuine cases can be established, and such separated from what must be spurious cases reported almost daily in the press.

I am, Sir, yours faithfully,

H. B. NEWHAM, M.D.

WHY ARE MEDICAL BOOKS WRITTEN?

To the Editor of THE LANCET.

SIR,—You begin a leading article in your issue of Jan. 2nd, entitled "The Literature," by saying that "a sign of the times is the growth of an immense literature (so-called) at every point where scientific progress is being made." I am moved to ask—why are medical books written? This question must arise very frequently in the minds of the medical booksellers who are supplied with catalogues by the various publishing firms. The bookseller sees on the one hand a long and elaborate "Handlexicon," and "Arbeitsmethoden" from Germany, and on the other the loose-leaf text-books of medicine, surgery, &c., from America, or the small and insignificant pamphlet-like books on "recent advances" from England. The meditative bookseller on receiving copies of these works and turning them over in the slack periods must wonder what object the authors had in view. Perhaps the most astonishing authors and publishers are those from Germany. The vast and expensive "systems" or "methods," running in some cases into hundreds of Lieferungen and dozens of volumes, make it difficult for the ordinary person, be he publisher, medical man, or general reader, to appreciate the aim of production. It is impossible to believe that the mere making of mone object of these serious works, since it is w that a semi-medical text-book, to be sol medical profession only," on, say, modern in marriage, will achieve the fortunes of the and author much more rapidly and with less effort. It is also puzzling to know fr the money comes to publish these very works, as we are told that Germany is ruined and yet it is the only country able t such volumes. Another type of book wh puzzle the retailer is that on some abstrus written by an unknown and junior man. however, a belief that when a young man and obtains a position on the staff of a ho a registrar, the writing of a book would d great deal of good. He therefore writes a through the influence of one of his seniors or a wealthy relative, persuades the publisher to it for him. Undoubtedly the work inv looking up the original literature, if he bothe this, will have benefited the author, but too o suffered is such as to make everyone wonder w result and published.

A SOURCE OF ERROR IN MEASUREMENTS OF URINE SECRETION.

To the Editor of THE LANCET.

SIR,—Drs. Kerridge and Ellis (THE LANCET, Jan. 9th, 1932, p. 83) have fortified the old-fashioned obstinacy of those of us who have long felt examination of the "twenty-four hour specimen" of urine to be a better clinical guide than any *ad hoc* "renal efficiency" test. But surely they are in error in suggesting that in "the prone position" micturition incompletely empties the bladder. Usually, of course, micturition in bed takes place in the *supine* position.

I am, Sir, yours faithfully,

Jan. 8th, 1932. CAVILLATOR.

OBITUARY

TOM BIRD, M.R.C.S., M.A. Oxf.

WE regret to announce the death, which occurred on Jan. 3rd at his residence at St. Margaret's-on-Thames, of Mr. Tom Bird, consulting anæsthetist to Guy's Hospital and the East London Hospital for Women.

Mr. Tom Bird, who was born in 1844, was educated privately, and entered Oriel College, Oxford, in 1862. He graduated in Arts but never joined the medical school, proceeding to Guy's Hospital, and taking the diploma of M.R.C.S. in 1869, at which date, and for long after, the single qualification was sufficient for the purpose of registration. He entered general practice, but being appointed anæsthetist to his old hospital he gradually became a specialist along this line, lecturing in the medical school and instructing the students at Guy's in his subject. He later became also anæsthetist to the Dental Hospital of London, the Hospital for Women in Soho-square, and the East London Hospital for Women, and obtained wide professional popularity as an administrator.

We owe to the courtesy of Mr. C. H. Golding Bird (not, by the way, a relative) the following note on Mr. Tom Bird as a professional colleague:—

"The recollection of Mr. Tom Bird as an anæsthetist, that I retain, has always been a pleasant one, for both privately and professionally he was a gentleman of unfailing courtesy. Quiet, refined—one may add dignified—in his manner, he at once impressed his patient with confidence, whilst the surgeon with whom he worked always felt that in his hands there was no undue anxiety in regard to his patient. His were the days of chloroform, ether, and A.C.E., and none of the present-day drugs of refinement in anæsthetics, or complicated appliances, were in use, so that, if possible, more care in the administration of the anæsthetic was then required of the administrator than at present. Tom Bird never took risks, and always warned the operator if he felt that the border-line of safety was being neared; on the other hand, he was by no means an over-anxious or hesitating administrator. He was much valued at Guy's as a teacher; he impressed his pupils by his manner, and never spared trouble in explanation and demonstration, always, however, exacting from them the closest attention to every detail. He was therefore much valued on the teaching staff, and nothing but the lapse of years caused his resignation, a matter of great regret both to his colleagues and the students he so well instructed."

A correspondent, a personal friend of Mr. Tom Bird, writes: "A few remarks on Tom Bird may be

hospital and are sent to the statistical branch ie public health department at County Hall, e they are punched, for tabulating purposes, and passed through a counting machine. This iine, a four-column sorting counter, will count iumber of holes punched in each of four columns e rate of 20,000 cards per hour. If, for instance, is desired to know how many patients were ed in the various types of ward, how the nts were admitted, how they were discharged, the reason for their discharge, the machine would et to count on certain columns. If, in addition, rards, for instance, were required to be examined rately in respect of other data, the machine would et to sort on column 14, in which numbers 0 to rrespond respectively to maternity, mental and rvation, venereal, tuberculosis, isolation, general ical, and general surgical wards, and would rer the cards in separate packs for each class of l.

ie standard procedure, adopted in the Council's ral hospitals is that bed cards are kept at the l of the patient's bed, but clinical notes are kept he charge of the ward sister; prescriptions diets are entered on the bed card, so that the case rs need never leave the wards. While for istical material prepared for the service as a whole lity is unavoidable, considerable elasticity is wed in the type of printed forms used by individual pitals. A form of report for the information of school medical service upon elementary schooldren treated in the general hospitals has been pted by the Committee.

he Committee on the *Staffing of Transferred itutions* reported a consensus of opinion that the ices of consultant staff should be freely available the patients in the Council's hospitals, but laid n no definite policy in regard to the best method mployment of such staff. Consideration was given this connexion as to how the Council's hospital rice could best assist in the provision of well ined and experienced medical men as private ctitioners. The Committee believe that owing the difficulty of obtaining resident appointments the teaching and other well-known hospitals, ie men and women enter private practice nediately after qualification without the advantage residence in a hospital; they recommended that far as possible resident house physicians or house geons or clinical assistants (non-resident) should employed at all the general hospitals in order provide opportunities of hospital experience.

They recommended that candidates for the post assistant medical officer should have already held resident hospital appointment, and that besides good general knowledge of institutional work they ould have begun to take a special interest in some rticular branch. In order to prevent the retention mediocrity in the service, it was strongly recomended that appointments to the grade of assistant lical officer should be for a limited period, which, was suggested, should be for not more than four ars. At the end of this service the appointment an assistant medical officer should be terminated less he had applied for inclusion in, and had been cepted for the "*promotion list*"—i.e., a list of imes of those considered suitable for and awaiting icancies in the grade of senior assistant medical licer. It was further recommended that provision iould be made for a free interchange of medical aff between all the hospitals.

The remuneration suggested by the Committee for a medical superintendent ranged from £900 with varying maxima to £1650, together with an unfurnished house.

THE COUNCIL'S ADMINISTRATIVE SCHEME.

In framing an administrative scheme the Council endeavoured as far as possible to provide that the transferred services should be merged in the Council's existing organisation and allocated to the committees of the Council to which they were appropriate.

Having regard to the varied character of the cases dealt with at the several institutions under its control and the manner in which the accommodation for such cases was distributed, the Council felt that it would not be desirable, even had it been practicable, to earmark particular institutions for specified purposes, and that any attempt to do so would seriously prejudice the formulation of a scheme for reclassifying and otherwise dealing with the transferred institutions. Before any such scheme could be prepared, it would have been necessary for a complete survey to be made of the existing buildings and the nature of the accommodation thereat. The Council was, however, in agreement with the principle enunciated in Section 5 of the Local Government Act, 1929, as to the desirability of making arrangements for the full exercise of the powers under the special Acts at the earliest possible date. It therefore decided to include in the administrative scheme a general declaration that it was the intention of the Council that, as soon as circumstances permitted, all assistance which could after April 1st, 1930, be provided either by way of poor relief or by virtue of any of the special Acts mentioned, other than the Maternity and Child Welfare Act, 1918, should be provided exclusively by virtue of the appropriate special Act, and not by way of poor relief. This would be in accordance with one of the main objects of the Act—to secure that as soon as practicable the existing duplication of powers should be brought to an end, and that each form of assistance should be in the hands of one, and not more than one, branch of the Council's organisation.

As regards the administration of the Maternity and Child Welfare Act, 1918, the position in London is complicated owing to the fact that the City Corporation and the metropolitan borough councils are the authorities under the Act. The Council proposes to give further consideration to this whole matter at a later stage.

Central Public Health Committee.—A very considerable part of the transferred work fell within the purview of the Public Health Committee, the membership of which was enlarged; members who were not members of the Council were coöpted and the reconstituted Committee was designated "The Central Public Health Committee."

The Committee deals, inter alia, with the provision, classification, maintenance, and management of hospitals for the sick, other than mental hospitals, and arranges for their visitation, and assumes responsibility for a number of children under 3 years of age formerly in the receiving homes and schools of the guardians.

For the purpose of hospital administration, the county was at first divided into five areas. Later this division was abandoned, but the preparation of statistics for this volume was already well advanced, and this early classification is retained in presenting some of the statistics and other information given in this report.

The questions involved in the separation of the able-bodied poor from the sick, especially in view of

PUBLIC HEALTH SERVICES

LONDON COUNTY COUNCIL.

ANNUAL REPORT OF THE MEDICAL OFFICER OF HEALTH FOR 1930.

BETWEEN the closing of office hours on the evening of March 31st and the morning of April 1st, 1930, 76 hospitals and institutions, containing over 42,000 beds and a staff of nearly 20,000, were transferred to the public health department of the London County Council. Prior to that date they had been administered by the late Metropolitan Asylums Board and the 25 Metropolitan Boards of Guardians, and thereafter they constituted one great hospital service under central direction and control.

In his first report[1] on the work of the hospitals and institutions transferred to the Council, Sir Frederick Menzies gives some account of how this great task was achieved. The basis of the smooth transference was the realisation that changes of procedure should not be too hastily made. Much preliminary work had been done in anticipation of the change, and many conferences had been held; meetings of medical superintendents, matrons, and stewards had been convened, and six months before the appointed day the head office staff had been strengthened by the appointment of a matron-in-chief and three principal medical officers. During the course of the year, it has been necessary to appoint four senior medical officers in the General hospitals division, and one (divisional) medical officer was newly appointed to assist the principal medical officer of the Special hospitals division.

One of the earliest major problems which faced the department was the difficulty in obtaining nurses, whether qualified or probationer, to fill vacancies as they arose. Consideration was next given to the best way of examining various important matters on which comprehensive reports would eventually have to be submitted to the Central Public Health Committee. It was decided to try experimentally the appointment of departmental committees representative of all the interests concerned to act in an advisory capacity; the first five committees appointed considered the treatment of tuberculosis, forms and records, the ambulance service, medical supplies, and pathological laboratory facilities respectively.

(Continued from previous page.)

interesting to your readers, for he had long outlived most of his professional contemporaries. Bird, outside his professional work, lived in the typical environment of mid-Victorian society. He had a small private practice, most of his patients being his friends or their relatives, and to these he was a wise and considerate adviser. He had a very attractive manner and appearance, and was popular in Mayfair and Bohemia. As a young man he had been a good oar—he was captain of his college boat club—and an adept skater. Until advanced life he had consulting rooms in Conduit-street, where he saw patients by appointment, but for several years he had entirely retired from practice and lived in the country. He will be missed by many of his juniors, especially at the United University Club where he was an habitué."

DEPARTMENTAL COMMITTEES.

The experiment proved successful and later committees were appointed on hospital standards; the staffing of transferred institutions; on medical appointments; on appointments to th intermediate grades of nursing staff (above sta nurse and below assistant matron) and of scho nurses; and to the senior grades of domestic staff The personnel of all these committees is described some of them included experts on the subjects unde consideration not in the service of the Council.

One of the most important perhaps from the poi of view of hospital management throughout th country is that on *hospital standards.*

The terms of reference were: to consider wh general standards, if any, should be adopted for th structure, equipment, and maintenance, includin staffing and methods of heating, lighting and ventil tion, of the public hospitals of London; and t consider also what hygienic standards, if any, shou be adopted for the institutions, homes, or poor la schools transferred to the Council under the Loc Government Act, 1929.

The members of the Committee are: *London Coun Council:* Dr. W. A. Daley (Chairman); Dr. V Brander; Dr. J. A. H. Brincker; Dr. H. Nockold Dr. W. T. Gordon Pugh; Mr. R. Robertson; an Mr. F. R. Hiorns. Mr. R. Coleman (Secretary *Ministry of Health:* Dr. Seymour and Mr. Scot *Director of Central Bureau of Hospital Informatio* Mr. R. H. P. Orde.

It is believed to be the first body representati of architectural and medical opinion set up in th country to study scientifically the problems of hospit construction and administration. After a prelimina study of existing conditions in hospitals at home a abroad the Committee considered such matters as a and bed space standards, and the best lay-out of war for the acute sick, maternity cases, children's sectio and isolation units. A plan was also prepared of model operating theatre unit. Its recommend tions are provisional at present, but are placed record as a basis of discussion. Various types ward accommodation and plans have been prepar to illustrate suitable lay-outs of ward blocks f different types of cases.

The Committee also considered carefully th question of standardising certain items of hospit furniture and equipment; its work is likely to exter over a considerable period of time.

To the Departmental Committee on *Forms a Records* was entrusted the task of considering wha were the most suitable books, forms and records t be kept in, or in connexion with, the transferr hospitals, including not only medical case-papers an all forms relating to medical work, forms f admission and discharge, notice to patient's friend but also statistical returns. One outcome of t deliberations of this Committee was the decis to use mechanical tabulation in the Council's hospita Some of the interesting results obtained from th returns thus compiled are appended to the repor and the possibilities for statistical investigation a obviously greatly increased by the adoption uniform records.

The standard form of card used is reproduced black spots indicating the position of punched holes which correspond with the entries on the card.

The cards are entered up from the case-papers a

FRIDAY, Jan. 22nd.—4 P.M., Mr. C. Gill-Carey: Rhinological Aspects of Asthma.

PETER'S HOSPITAL, Henrietta-street, W.C.

WEDNESDAY, Jan. 20th.—3 P.M., Mr. J. Swift Joly: Examination of Urological Patients.

AL INSTITUTE OF PUBLIC HEALTH, 37, Russell-uare, W.C.

WEDNESDAY, Jan. 20th.—4 P.M., Sir William Willcox: Ætiology of Rheumatism, with Special Reference to Infective Causes.

AL MATERNITY AND WOMEN'S HOSPITAL, Glasgow.

WEDNESDAY, Jan. 20th.—4.15 P.M., Dr. S. J. Cameron: Obstetrical Cases.

ULTY HALL, St. Vincent-street, Glasgow.

TUESDAY, Jan. 19th.—4 P.M., Prof. C. Browning: Serological Tests and Their Significance.

Appointments

ifying Surgeons under the Factory and Workshop Acts: Macintyre, T. G., L.R.C.P., L.R.C.S. Edin., L.R.F.P.S.G. (Tobermory, Argyll); McShane, C., M.D., Ch.B. Belf. (Barking, Essex); Middleton, G. P., M.B., Ch.B. Edin. (Ballater, Aberdeen); Lakin, F. H., M.B., Ch.B. Aberd. (Burghead, Moray); Richard, F. L., M.B., Ch.B. Glasg. (Walsall); and Williams, J. (Richmond, York).

Vacancies

or further information refer to the advertisement columns.

kenham, Kent, Bethlem Hospital, Monks Orchard.—Res. H.P. At rate of £150.

mingham, City Mental Hospital.—Sen. Asst. M.O. and Deputy Med. Supt. £550.

mingham, Little Bromwich Hospital for Infectious Diseases.—Jun. Asst. M.O. £300.

tol Royal Infirmary.—Hon. Gynæcological Reg.

diff Royal Infirmary.—Two H.P.'s and Two H.S.'s. All at rate of £50.

nbridge, Papworth Village Settlement.—Third Asst. M.O. £200.

y of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—H.P. At rate of £100.

adnought Hospital, Greenwich.—Hon. Dermatologist.

stbourne, Princess Alice Memorial Hospital.—H.S. At rate of £150.

gow Corporation.—P.H. Dept. Pathologist. £800.

mpstead General and N.W. London Hospital, Haverstock-hill, N.W.—H.P. At rate of £100.

rrogate General Hospital.—H.P. £150.

rrogate Infirmary.—Sen. H.S. £150.

Hertford County Hospital.—H.P. At rate of £150.

King Edward Memorial Hospital, Ealing.—Jun. H.S. £150.—

L.C.C.—Sen. Asst. M.O.'s for Hospital Service. Each £500.

Leeds Hospital for Women.—H.S. At rate of £100.

Leicester, City Mental Hospital, Humberstone.—Second Asst. Res. M.O. £400.

Liverpool and Samaritan Hospital for Women.—Hon. Asst. Surgeon.

Liverpool, David Lewis Northern Hospital.—Four H.S.'s and Two H.P.'s. Each at rate of £100.

Liverpool Eye and Ear Infirmary.—Ophth. H.S. £120.

Manchester City.—Asst. Tuber. O. £650.

Manchester, Radium Institute.—Asst. M.O. At rate of £400–£500.

Manchester, St. Mary's Hospitals.—Four H.S.'s and Jun. Asst. M.O. All at rate of £50.

Manchester, Withington Hospital.—Asst. M.I. £300.

Mile End Hospital, Bancroft-road, Mile End, E.—Asst. M.O. £350.

National Hospital, Queen-square, W.C.—Hon. Surg. Asst.

Newcastle General Hospital, Newcastle-upon-Tyne.—Res. Med. Assts. Each at rate of £150.

Northampton General Hospital.—Hon. Ophth. Surgeon.

Queen's Hospital for Children, Hackney-road, E.—Surg. to Ear, Nose, and Throat Dept.

Retford, Notts, Rampton State Institution for Mental Defectives.—Fourth M.O. £400.

St. Alfege's Hospital, Vanbrugh Hill, Greenwich, S.E.—Asst. M.O. £350.

St. John's Hospital, St. John's Hill, S.W.—Asst. M.O. £350.

St. Mark's Hospital for Cancer, Fistula, and Other Diseases of the Rectum, City-road, E.C.—H.S. At rate of £75.

St. Mary Abbot's Hospital, Marloes-road, Kensington.—Asst. M.O. At rate of £250.

St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—Anæsthetist. £25.

Sheffield Children's Hospital.—H.S. and Cas. O. At rate of £80.

—Ophth. H.S. At rate of £80.

for Women, Clapham Common, S.W.—Surg. Reg. 50 guineas. H.S. At rate of £100. Also Anæsthetist 10*s.* 6*d.* per attendance.

Swindon and North Wilts Victoria Hospital.—Res. M.O. £125.

Weir Hospital, Grove-road, Balham, S.W.—Jun. Res. M.O. £150.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Sen. Res. H.S. At rate of £150.

West London Hospital, Hammersmith-road, W.—Non.-Res. Cas. O. £250. Also Hon. Obstet. Reg.

Windsor, King Edward VII. Hospital.—H.S. At rate of £100.

Worcester General Infirmary.—Jun. Res. M.O. £120.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Petersfield (Hants), Hoddesdon (Herts), Malvern (Worcs.), Pontrhydygroes (Cardigan), Shaftesbury (Dorset), Bexhill (Sussex), Lyndhurst (Hants), Modbury (Devon), Alresford (Hants), and Cranborne (Dorset).

Workmen's Compensation Act: Medical Referee for Wolverhampton (Circuit 25). Applications should reach the Private Secretary, Home Office, Whitehall, not later than Jan. 30th.

Births, Marriages, and Deaths

BIRTHS.

AMOR.—On Jan. 8th, at The Cottage, Clydach, Swansea, the wife of Arthur J. Amor, M.D., of a daughter.

WARNER COLLINS.—On Jan. 9th, 1932, at Chartfield, Putney, S.W., to Leona, wife of Dr. Warner Collins—a daughter.

EDMONDSON.—On Jan. 5th, at Dalkeith House, Clarendon-place, Leamington Spa, the wife of Dr. Edmondson, of a son.

SHACKLE.—On Jan. 5th, the wife of J. W. Shackle, M.R.C.S., L.R.C.P., of Ardanoir, Purley Bury Close, Purley, of a son.

WIGHT.—On Jan. 3rd, the wife of Cecil H. Wight, M.C., M.R.C.S., L.R.C.P., of Wangford, Beccles, of a son.

MARRIAGES.

WILLIAMS—PRATT.—On Jan. 9th at St. Stephens, Lewisham, Harry Bowen Williams, M.D. (Brux.), M.R.C.S., L.R.C.P., of Brockley, S.E., to Cassie Ethel Pratt, M.R.C.S., L.R.C.P., of Bexley Heath and Jerningham-road, New Cross, S.E.

DEATHS.

GREVES.—On Jan. 12th, following an operation, Edwin Hyla Greves, M.D., F.R.C.P., of Rodney House, Bournemouth. Funeral service at St. Michael's Church, Bournemouth, on Friday, the 15th, at 2 o'clock.

PRICE.—On Jan. 8th, at Guernsey, Spital-road, Maldon, Henry James Price, F.R.C.S., London, aged 77.

VAUGHAN.—On Jan. 5th, in London, Colonel Joseph Charles Stalke Vaughan, I.M.S., C.I.E.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages and Deaths.

UNIVERSITY OF LONDON MEDICAL GRADUATES SOCIETY.—An afternoon meeting of this society will be held at the London School of Hygiene and Tropical Medicine, on Thursday, Jan. 21st, at 4 P.M., when demonstrations and films will be shown and tea will be served. All medical graduates of the University are invited, whether members or not. Tickets are obtainable from the hon. secretaries of the society at 11, Chandos-street, W.1.

the varying degrees of sickness, were found very difficult of settlement, and before coming to any conclusions it was found desirable to attempt a definition of what was meant by "the sick." For this purpose it was considered convenient to divide all persons receiving medical and nursing attention in the poor-law hospitals and mixed institutions into the following classes:—

(1) Patients needing continuous medical or surgical treatment (acute sick);
(2) Patients needing institutional treatment because they are suffering from some chronic disease, also aged and infirm persons requiring medical and nursing attention (chronic sick);
(3) Maternity patients (excluding infants) (acute sick);
(4) Mental patients (acute sick);
(5) Healthy infants (under 3 years of age), excluding those in the maternity wards.

For the accommodation of the acute and chronic sick it was considered desirable that two types of hospitals should be recognised—viz., hospital "A" for the acute sick and hospital "B" for the aged and infirm and those suffering from chronic disease.

Acute sick.—Examination of statistics of patients in relation to the number of beds available in hospitals in various areas led to the conclusion that although a central administration of all the hospital beds and rearrangement of accommodation would, it was anticipated, bring about a higher average occupation generally, yet the available accommodation for the acute sick would be inadequate for future needs.

Chronic sick in mixed institutions.—The types of inmates in the mixed institutions included:—

(1) Aged persons who are up and about;
(2) Aged persons and others who are suffering from debility, chronic bronchitis, chronic rheumatism, chronic heart and arterial disease, and chronic kidney disease, &c.;
(3) Paralysis cases;
(4) Cancer cases;
(5) Mental defectives and epileptics.

It was difficult among this heterogeneous mass of chronic sick, aged, and infirm persons, to define accurately the degree of infirmity or disability that places a person in the category of the "sick."

The Administrative Scheme did not place under the direction of the Committee any institution of the mixed type, but with the concurrence of the Public Assistance Committee, it was agreed that 12 institutions with accommodation for over 2500 should be allocated as hospitals to provide for the "chronic sick."

The proposed allocation left, for the time, accommodation for "healthy" cases (approximately 2770) in the hospitals under the Central Public Health Committee, and accommodation for "chronic sick" (approximately 5120) in the *institutions* under the direction of the Public Assistance Committee. In order to allow time, which may be considerable, for reorganisation and reclassification, the agreed allocation was regarded as provisional only.

(*To be concluded.*)

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JAN. 2ND, 1932.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 54 (last week 32); scarlet fever, 1579; diphtheria, 910; enteric fever, 40; pneumonia, 2139; puerperal fever, 20; puerperal pyrexia, 105; cerebro-spinal fever, 33; acute poliomyelitis, 6; acute polio-encephalitis, 1; encephalitis lethargica, 7; dysentery, 15; and ophthalmia neonatorum, 92. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals o London County Council on Jan. 5th–6th was as foll Small-pox, 82 under treatment, 8 under observation (week 75 and 1 respectively); scarlet fever, 1329; diphthe 1510; enteric fever, 7; measles, 661; whooping-co 431; puerperal fever, 16 (plus 11 babies); enceph lethargica, 224; poliomyelitis, 2; "other diseases," At St. Margaret's Hospital there were 20 babies (plus mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, inc London, there were no deaths from small-pox, 1 from enteric fever, 47 (14) from measles, 1 (1) fr scarlet fever, 48 (11) from [illegible] diphtheria, 81 (22) from d [illegible] two years, and 240 (53) from influenza. The figu in parentheses are those for London itself.

Eight of the cases of measles were reported f Manchester and 6 from Stoke-on-Trent. Whooping-co caused 8 deaths in Birmingham and 6 in Liverpool. Ele of the fatal cases of diphtheria were in Hull and 5 Liverpool. Diarrhœa and enteritis accounted for 7 dea in Liverpool, 6 in Manchester, and 4 in Cardiff. Of deaths attributed to influenza, 17 were in Manchester 11 each in Birmingham and Liverpool.

The number of stillbirths notified during the w was 289 (corresponding to a rate of 44 per 1000 t births), including 46 in London.

Medical Diary

Information to be included in this column should reac in proper form on Tuesday, and cannot appear if it re us later than the first post on Wednesday morning.

RING and vision are the two senses which give
information of the visitant world. Taste,
and muscle-sense tell man only of things with
he is in immediate contact, and smell, though
for information for remote objects, does not
him greatly in that capacity. The world of
rson who is both deaf and blind is pitifully
The deaf-blind moves in the larger world,
not of it.

tragedy of blindness is widely recognised,
e the disabilities of blindness are frequently
it home to normal people when they find
lves in darkness. But deafness strikes no cord
the deaf are at the very least
the blind, for deafness is isolation
in a large world the joy of which
s from social contact. The deaf much more
he blind are thrown on to their own resources.
iousness, the most precious of joys, is denied
m. They stand outside the pale. The blind
in the melée of life. The deaf always move in
on.

n Keller, herself blind, deaf and dumb, rates
orror of deafness above that of blindness.
problems of deafness" she says, "are deeper
ore complex, if not more important, than those
dness. Deafness is a much worse misfortune.
means the loss of the most vital stimulus—the
of the voice—*that brings language, sets thought
and keeps us in the intellectual company of man.*"
tial deafness is a much greater disability than
l blindness, and the lesser degrees of auditory
are much more crippling to social and individual
than the lesser degrees of visual defect.
e in vision will certainly handicap a man in
lised work for which full visual acuity is
sary, but decline in hearing hinders social life
very-day duties.

the problem of deafness is as urgent on the
dual side as that of blindness, it is equally
t as a social problem, for deafness and auditory
take as large a numerical toll as blindness
visual defect. Statistics with any approach to
acy are not available for the general population,
the figures supplied by the school medical
e for 1927 are of interest.[1] Thus there were
ngland and Wales, 1925 totally blind children,
ver twice as many totally deaf children, namely
In the case of partial defect, the proportions
eversed: as against 4929 partially blind, there
2053 partially deaf children. The extent of
r auditory defect is far greater than is generally
ined, though it is not so great as that of minor
l defect. Thus, repeated examinations at
ls reveal some degree of visual defect in about
er cent. of children. The extent of auditory
t seems to vary with the type of school popula-
It is generally given as about 25 per cent.
ildren. Thus, Barr (Glasgow, 1890) found it to
7·66 per cent.; Bezold (Munich, 1885), 25·8 per
, and Denker (Erlangen, 1906), 23·3 per cent.,
es which agree closely with the 29·5 per cent.
d by Dr. Mable Russell[3] in 1930, in a group of
unselected children in the London County Council
ols. The extent of deafness in the adult popula-
is unknown, but there can be no doubt it is much higher than the 25–30 per cent. seen in school-children. The problem of the deaf is much larger than is generally imagined.

The Causes of Deafness.

No doubt the majority of cases of partial deafness are due to acquired causes. Analyses of available statistics concerning children whose hearing is sufficiently defective to require their attendance at a deaf school shows that acquired causes are responsible for a proportion varying between 35 to 75 per cent. (see Table I.).

TABLE I.—*Showing Proportions of Congenital to Acquired Deafness in Schools for Deaf Children.*

Source.	Deaf children examined.	Born deaf.	Acquired.	Unknown.
		Per cent.		
Glasgow Institution for the Deaf (Kerr Love)[1]	214	52·8	44·5	2·3
National Institute of the Deaf (1928)[1]	2946	56·0	35·0	9·0
Amer. Annals of the Deaf[1]	4649	44·0	44·0	12·0
(American) National Research Council[4]	5348	62·3	—	—
L.C.C.[2]				
1909–17.. ..	1863	35·1	60·0	4·9
1919–28.. ..	1630	24·7	68·0	7·3
1929–30.. ..	277	21·7	75·1	3·2

The conflicting nature of the figures in this Table is no doubt due to the different standards employed by different bodies for the admission of children to deaf schools. The relatively low proportion of children born deaf in the L.C.C. figures is due to the care bestowed by the L.C.C. on the partially deaf children by admitting them to the special schools. For the understanding of the possibilities in the prevention of deafness it is necessary to analyse the causes in greater detail.

CONGENITAL DEAFNESS.

A child born deaf may be the victim of frankly hereditary forces or of an obscure lesion. Hereditary deafness is assumed when the family history points in that direction; sporadic congenital deafness when no such influence is obvious. Aphasia is responsible for a small number.

The relative proportion of hereditary to sporadic deafness varies with different statistics. The L.C.C. figures for 1919–1928 report 83 true hereditary deaf against 305 sporadic deaf-born. The line of division between the two is not always easy. The existence of a deaf relative, or even of a deaf parent, is no proof that the new-born child is the subject of hereditary deafness; nor, paradoxical as it sounds, is the absence of deafness in the parents evidence that the deafness is not hereditary, for the parents may be carriers of deafness without themselves being deaf. It is the family history extending to many generations, with undisputed evidence of deaf-mutism, that constitutes conclusive evidence of true hereditary deafness. It is more than possible that some forms of deafness in adults have a familial tendency, but the predisposition to deafness developing in adult life is something distinct from deafness at birth, with its consequent dumbness.

The problem of hereditary deaf-mutism was sharply focused in 1883 by Graham Bell, in his classical memoir on "The Formation of a Deaf Variety of the Human Race."[5] Bell pointed out that, of the "2262 congenital deaf-mutes, more than half, or 54·5 per cent., had deaf-mute relatives; and in the case of those pupils who became deaf from apparently

MEDICAL NEWS

Royal College of Surgeons of England.

Forthcoming lectures at the College begin with six by Sir Arthur Keith on Malformations of the Human Body considered from a New Standpoint. These will be given at 5 P.M. on Mondays, Wednesdays, and Fridays, from Jan. 18th to 29th. The other Hunterian lecturers are Mr. J. P. Hosford on Some Factors in the Causation of Hydronephrosis (Feb. 1st); Mr. R. T. Payne, on Excretion Urography (Feb. 3rd); Dr. Remington Hobbs, on Puerperal Sepsis (Feb. 5th); Dr. J. A. Ryle, on the Natural History of Duodenal Ulcer (Feb. 8th); Prof. H. A. Harris, on the Comparative Anatomical Aspect of the Prenatal, Infantile, and Adult Disease in Man and Animals (Feb. 10th and 12th); Prof. W. Le Gros Clark, on the Structure and Connexions of the Ophthalmic Thalamus (Feb. 17th and 19th); and Dr. A. J. E. Cave, on the Morphological and Functional Anatomy of the Human Cervical Spine (Feb. 22nd). As we have already announced, Mr. Wilfred Trotter will give the Hunterian oration on Monday, Feb. 14th, at 4 P.M. All the other lectures mentioned are at 5 o'clock

University of Liverpool.

At recent examinations the following candidates were successful:—

D.P.H.

A. Ashworth, Elizabeth M. Harding, R. L. McMorris, J. S. Mather, W. J. Pierce, J. H. Pottinger (with distinction), and A. J. Walsh.

British Medical Association: Scholarships and Grants in Aid of Scientific Research.

The Council of the British Medical Association is prepared to receive applications for *Research Scholarships* as follows: an Ernest Hart Memorial Scholarship, of the value of £200 per annum, and three Research Scholarships, each of the value of £150 per annum. These Scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State Medicine) relating to the causation, prevention, or treatment of disease. Each scholarship is tenable for one year, commencing on October 1st, 1932. A scholar may be reappointed for not more than two additional terms, and is not necessarily required to devote the whole of his or her time to the work of research, but may hold University or other appointments, provided the duties do not interfere with his work.—*Grants:* The Council of the Association will receive applications for Grants for the assistance of research into the causation, treatment, or prevention of disease, when preference will be given to applicants who propose as subjects of investigation problems directly related to practical medicine. Applications for these Scholarships and Grants must be made not later than Saturday, May 21st, 1932, on a form, supplied on application to the Medical Secretary of the Association, B.M.A. House, Tavistock-square, London, W.C.1. They must be accompanied by the names of three referees, competent to speak to the capacity of the applicants for the researches proposed.

Society for Relief of Widows and Orphans of Medical Men.

A quarterly court of the directors of this society was held in London on Jan. 6th, with Mr. Warren Low, the president, in the chair, and three new members were elected. The death of one of the widows was reported. She had been in receipt of grants since 1897, and had received a total of £3100. Her husband was elected a member of the Society in 1856 and died in 1897, having paid some £52 in subscriptions. A sum of £1695 was voted for the half-yearly grants, to be distributed among the 49 widows and six orphans in receipt of grants, and a further £112 10*s.* as special grants to five orphans over the age of 16—at which age the ordinary grants cease—to enable them to continue their education. The expenses of the past quarter were about £88. It was decided that at the next court the best means of making the society better known should be thoroughly discussed, since many medical men, it was stated, are unaware of its existence. Membership is open to any registered medical man who at the time of his election lives within 20 miles of Charing Cross. The annual subscription ranges from 2 to 4 guineas, according to the age of the member at the time of his election. Relief is granted only to the widows and orphans of deceased members. Further particulars may be had from the offices of the society at 11, Chandos-street, Cavendish-square, W. 1, where the secretary attends each Wednesday and Friday between 4 and 5 P.M.

London School of Hygiene and Tropical

Dr. James Fenton, medical officer of health for Kensi has been appointed an additional lecturer on public administration and practice, and Mr. L. W. G. Malc conservator of the Wellcome Historical Medical Mu to be a lecturer on racial hygiene. Both appointment honorary.

King Edward's Hospital Fund for London.

The King has sent a contribution of £1000 to the F being his annual subscription.

The Prince of Wales, as President of the Fund, appointed the following new members of the Ho Economy Committee: Miss Margaret Bigge, Dr. Thursfield, and Commander Alfred Williams.

Royal Microscopical Society.

At the annual meeting of this society, to be held at B.M.A. House, Tavistock-square, London, W.C., at 5.30 P.M., on Wednesday, Jan. 20th, Prof. R. Ru Gates, F.R.S., will give a presidential address on Nu Structure.

Hunterian Society.

Prof. A. von Eiselsberg, of Vienna, will delive Hunterian lecture of this society at a meeting at Apothecaries' Hall, Water-lane, E.C., at 9 P.M. on Mo Jan. 18th. The annual dinner will be at the May Hotel on Thursday, Feb. 11th.

Post-graduate Lectures on Sundays.

Because of the success of previous courses it has decided to hold another post-graduate course at Ch Cross Hospital Medical School on Sundays from Jan. to March 20th. Two lectures are given each day, at and 11.45 A.M. On Sunday next Dr. W. J. Adie will the series with an address on Early Symptoms of Co Nervous Diseases, and Mr. L. J. Broster will speak on Injuries. A fee is charged for the course, and appli should be made to the secretary of the School, 62, Ch street, London, W.C. 2.

Royal Sanitary Institute.

A health exhibition will be held at Brighton from 11th to 16th in connexion with the annual congress institute. The exhibits will be concerned, among things, with sanitary appliances, baths, and lava lighting, heating, decoration and furnishing of the bread, milk, and other foods and beverages; h appliances and labour-saving devices; apparatus appliances used in municipal administration; water-s disinfectants: and soaps. The address of the insti 90, Buckingham Palace-road, London, S.W. 1.

British Empire Cancer Campaign.

Sir John Bland-Sutton, vice-chairman, presided quarterly meeting of the Grand Council last Monday. following grants were approved: £3000 to the Mid Hospital for six months; £1500 to the Cancer H (Free) for six months; £150 to Dr. Thomas Lum £75 to Miss Goulston; and £17 10s. to Dr. H. P. Ba The Council received a report from the joint com of representatives of the campaign and the Mount Hospital nominating Dr. A. E. Barclay, lecturer in radiology in the University of Cambridge, to the radio research fellowship founded by Sir William Morris Mount Vernon Hospital.—A memorandum from the N Radium Fund was submitted to the Council aski coöperation of the campaign in a policy of confining treatment to those radium centres in provincial ho selected and approved by the National Radium Comm It was reported that a recent questionaire drawn the Central Bureau of Hospital Information showe there are three principal groups dealing with radi the present time: King E [illegible] administering radium to [illegible] politan area; the Nation [illegible] ing radium outside the [illegible] pendent group of over 100 centres established in ho of 50 beds and upwards in England, Scotland, and controlling approximately 16·8 g. There is also a co able quantity of radium owned privately by surge the country. The Grand Council resolved to coöpe far as practicable in helping the National Radium with its policy of radium distribution so that ever of the country shall be adequately served, and that for therapeutic purposes shall be in the hands only o well qualified to use it.—Mr. C. H. Fagge was unani elected a member of the Grand Council.

ADDRESSES AND ORIGINAL ARTICLES

COMMENTS ON SOME RECENT
CURSIONS IN THERAPEUSIS.*

SIR THOMAS HORDER, BT., K.C.V.O., M.D.,
F.R.C.P. LOND.,
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

HAVE decided to touch upon one or two of the e recent tendencies which have shown themselves he modern treatment of disease. Time permits y mentioning only a few of these, and, even so, ake but a glance at them. But this glance is not out interest, especially for those of us who, sadness be it said, can remember former things, so take a wider view than might otherwise be ible of the transitions taking place in this as in r parts of medicine.

have used the word "excursion" in the title of se remarks because I want to convey the idea t, with our limited knowledge of the causes of ase, and of the interactions produced in the y by these causes and the defensive mechanisms t are present, the most that any generation can in therapeusis is to make tentative inroads into se but partially unexplored regions, with the hope t some resultant benefit may accrue to our patients. netimes these excursions are rational, sometimes y are empirical, sometimes they have the elements great wisdom, and sometimes they are merely d adventures. They are the result of a widely erent series of impulses, which includes the know- ge accumulated by our predecessors, the discovery new facts in physiology, the provision of new tools chemistry, in physics, in mechanics, and indeed all the sciences, the temperament of the doctor, d the tolerance and credulity of the patient. For ake catholicity to be the essence of our outlook in rapeusis, as it is in medicine generally. Unless, course, we be Nature Curers, and do not believe in ugs; or Spiritual Healers, and do not believe in y material aids; or Homœopaths, and slaves to a rrow therapeutic doctrine; or follow some peculiar gue which, though it may tickle the popular agination for a time, cannot bring to the service the sick person what is surely his right to expect, e sum of all human knowledge that can possibly used on his behalf. No, I assume that we regard edicine as the child of all the sciences, and of all e arts, and therapeusis as the practical issue of edicine, directed towards the maintenance of human alth and happiness.

Therefore I omit from my survey this evening all ese limited cults, by which therapeusis is "cribb'd, bined, and confined." I also omit the various cursions that are from time to time made in that im borderland which lies between a legitimate stering of the patient's confidence—so valuable a erapeutic asset—and a gross exploitation of his ars and of his hopes. Among the 50,000 men and omen who practise medicine in Great Britain there ust needs be a few who have never quite mastered he spirit of the Hippocratic oath. Nor of the Golden ule. And there is that vexed question one is so ften asked as to whether a man may, by frequently epeating it, become convinced of the truth of something which is so obviously a lie! And charity bids us say "yes," though, when we see the fellow, and talk to him, the one thing certain is that he should never have been a doctor, but a politician! And so I omit Abram's Box, that nightmare which afflicted us a few years ago, and which I learn is still, like a rat in a hole, nibbling at the purse of that part of the public which thinks an instrument, however ill-constructed, is not likely to err like the fallible human brain. And I omit those Electrotherapeutics that are peculiar in that "no one has an installation like it." And "Bloodless surgery." And "Cheiropractics." And the latest drug from Berlin, "brought over on purpose." And even the exploits of the foreign "Professors" who have a special attraction for many patients because, not being British, they are thought to hold the keys of heaven and of hell in matters hygienic. In most of these excursions we catch sight of the cloven hoof, though the victims themselves elect to charge us with jealousy and ostracism. Credulity, like youth, must be served, and where the carcase is there will the vultures be gathered together. . . . .

Surgery and Endocrine Therapy.

Let me turn to things that really matter. I should like to speak of surgery, if I had time, since I do not agree with my distinguished friend, the President of the College, that even the *craft* of surgery has reached its zenith. Anyway, I am sure that he, too, believes that the *field* of helpful surgery is far from being exhausted. The assistance given to prompt and clean surgery by intravenous therapy and some allied measures is already revolutionising the treatment of shock, as this Society has recently heard during the presentation of the Buckston Browne prize essay. In the surgery of the sympathetic nervous system, of the thyroid gland, and in a number of other directions, the excursion is bold but already amply justified by results. I should also like to speak of endocrine therapy, and of the arrest of certain diseases in which there has been proved to be a loss of hormone control of metabolism, as in the affections associated with calcium dysfunction which formed the subject of Dr. Donald Hunter's recent demonstration to this Society. But all this would take much too long. I will deal only with two interesting and important excursions, and offer some comments upon them. They are the development of irradiation therapy, and the present position with regard to immuno-therapy.

X Rays and Radium.

The discovery of X rays in 1895, and the isolation of the rarer metals—and especially of radium—and their radiations between 1896 and 1901, placed in our hands therapeutic instruments of enormous value. X rays being first rendered available in practical fashion, their application in the treatment of disease preceded that of radium by several years, and until quite recently they constituted the more popular method of employing gamma rays therapeutically. Of late, however, the position has become reversed so much so that in several fields there seems a tendency to discount the value of X rays for purposes of treatment and to confine their usefulness to the field of diagnosis. This seems unfortunate seeing that, as it would appear, we had only just begun to explore the possibilities of X ray therapy at the time when radium therapy overtook the older method in sufficient space between the tufts, which should be wired to the framework—cemented bristles are a danger." He points out that dental floss and even the fine tooth-pick may find a place in the hygiene of the teeth, as proved by their scavenging results. But he points out that the public should receive instruction in using both these adjuvants and the tooth-brush itself, for lack of right methods may cause erosion of the enamel and, by irritating the gingivæ, lower the local resistance and thus hasten the onset of pyorrhœa alveolaris. How far this occurs frequently seems to be uncertain.

---

* Presidential address to the Harveian Society of London on an. 14th.

CAUSES OF EXCLUSION FROM SCHOOL.

AN interesting analysis of the numbers of children absent permanently or for long and short periods from school is included in the annual report for 1930 of Dr. H. Leslie Cronk, medical officer of health for Hampshire. He says in an introductory note:—

The survey of the health of children attending elementary schools in Hampshire shows clearly enough their conditions as regards dental decay, defective eyesight and hearing, and such deformities and defects which are not sufficient to prevent a child attending school. This makes a very imperfect picture, and leaves out all the ailments which are sufficiently severe to keep a child from school, and also those seemingly trivial but really somewhat important ailments from which children recover, and which leave no distinct signs to an inspection at school later on. To obtain a truer view of what health the children of this county enjoy, these two classes of ailments need to be reviewed. These words are of general application, for surveys of this kind should form an essential part of the study of the health of the elementary school-children of any area.

In Hampshire there are 44,506 children on the school register, and the average attendance is 40,415—that is, the average number of absentees is 4091.

Group I.: 231 children were permanently excluded from school for the following causes: 81 mentally defective; 15 blind; 29 deaf; 14 epileptic; 5 tuberculous; 1 suffering from deformity, 1 from respiratory disease, 6 from other diseases. In these lists children from 5 to 16 are included; without counting those above 14, the numbers would be much smaller, especially for the blind, deaf, and epileptic; and, apart from these groups and the mentally defective, there would be only 23 children permanently excluded from school.

Group II.: 400 children were absent from school for over three months at a time, equivalent to an average loss of 165 days throughout a year. The causes were:—

Disease.	Cases.	Weeks lost.
Infectious diseases	66	1137
Debility	53	1037
Rheumatic conditions	48	1199
Diseases of respiratory tract ..	47	964
Suspected tuberculosis	36	1038
Injury	28	538
Skin diseases and ringworm ..	27	485
Ear disease and mastoiditis ..	18	398
Appendicitis	11	192
Eye diseases	8	177
Diseases of genito-urinary system ..	6	108
Other conditions	42	995

The figures for infectious diseases were affected by a severe epidemic of measles. The amount of absence for suspected tuberculosis is high. It is noted that these figures do not imply "a large incidence of clinical tuberculosis among children." As a preventive measure, a certain number of ailing children, contacts of tuberculous patients, are received for treatment.

Of the 48 children said to be suffering from rheumatic conditions, 18 were suffering from chorea, and 12 from heart disease. It would be interesting to know how far this loss of attendance would be reduced in an area where there was a fully orga rheumatic scheme. Dr. Cronk says that in the cases are so scattered that supervision by sp clinics appears impracticable. He believes that provision of a convalescent home where educat can be given might be useful and might sequelæ, but it would necessarily be costly. T cases of injury occur most in boys of 7 and 8, a f which is interesting in relation to the Safety F campaign. Ringworm accounts for a number long absences, owing to the lapse of time bef obtaining the treatment by X ray provided.

In *Group III.* (absences of one week to months; ages 11 to 14 inclusive) the feature is the loss of time due to respiratory diseases

The numbers of absentees in Groups II. and III. were notably lower in schools where milk was given, and in general the provision of milk markedly reduced the loss of school attendance.

THE PRESCRIPTION OF GLANDULAR PREPARATIONS.

THE failure to differentiate between fresh and desiccated gland in prescribing glandular remedies may lead to ineffective dosage. In a booklet on Glandular Products and Their Doses, Mr. H. W Paines, M.P.S., gives useful advice about this. For ten years he has been engaged solely in dealing with these preparations, and he finds that the confusion in th minds of practitioners is getting worse. Whe thyroid was first introduced the fresh gland from th sheep was given, minced, in its raw state. The fir clinical experiments having been made with fres gland, this scale of dosage was carried on whe tablets containing desiccated gland were introduce and these were prescribed in terms of the equivale amount of fresh gland. The alternative is to prescri them in terms of the actual preparation used. Inste of writing: Thyroid fresh gland gr. i, one may p scribe thyroid siccum, gr. 1/5; and in the opini of Mr. Paines this is greatly to be preferred. T five names in common use are thyroid, thyroid fr gland, thyroid gland, thyroid extract, and thyr siccum. Pharmacists often have difficulty in int preting what is meant by some of these, and unl the last is employed the patient may get five tir or one-fifth of the dose intended. Mr. Paines co monly finds tablets in use with a totally inadequ dosage, and he lays down the rule that all glandu products should be prescribed in terms of the gland only. At the end of his booklet, which obtainable from Messrs. Paines and Byrne, L 31, Southampton-street, London, W. 1, he give table showing the "minimal therapeutic dose" a number of glands and the usual maximal d employed. This table would be of more value if had eliminated those substances of which the th peutic value in any dose is quite unrecognised. does not offer comments on the activity of preparations, but this clearly varies within limits.

ERRATUM.—In an article on Early English I Jars, published in THE LANCET of Dec. 26th, p. 1 the word "*caudle* cups" was misprinted "ca cups."

NATIONAL COUNCIL FOR MENTAL HYGIENE. association with the Howard League for Penal Re this council has arranged a series of lecture-discussion the Psychologist's part in the Prevention and Treatme Crime. They will take place at the rooms of the Me Society of London, 11, Chandos-street, W., at 5.30 P.M Wednesdays from Feb. 10th to March 16th. The series start with a lecture by Mr. George Ives on Penal Met Past and Present, after which the next two speakers wi Dr. T. S. Good, on Crime and Mental Abnormality, Dr. E. B. Strauss on the Borderline Case. Tickets ma had at the doors or from the secretary of the Counc 78, Chandos House, Palmer-street, S.W.1.

uld be foolish to suppose that we have seen the its of the method of active immunisation. We y have missed the optimum possibilities of the thod by just a little, and we may one day hit on, or stumble upon, some modification of our sent techniques which will make all the difference tween the frequent failures which cause so many be frank disbelievers to-day, and such uniformity good results as will convince the most sceptical. e suggestion that better results might be obtained we took pains to bring the antigen into more mediate and direct contact with the tissues which the main site of infection is only now being lowed up.

A new chapter has been opened quite recently in nnexion with bacteriophages. Concerning these, work so far done, both in the laboratory and the bedside, is too meagre to call for detailed mment.

Chemotherapy.

Chemotherapy received a marked fillip with rlich's introduction of 606. Within a few years ere was scarcely any infection that had not been ated by the method. No doubt many lives were t in consequence, though it is probably true to y that in most of these instances recovery would t have occurred had the remedy not been used. -day we do not regard the drug, nor its more odern equivalents, as being directly germicidal, as rlich did, and we have found that its indirect rmicidal effect is limited to a somewhat narrow ld. We are also beginning to realise, having given the ideal of a *therapia sterilans magna,* that the travenous route is by no means necessary, and may times be inferior to the older route of the muscles. ut the success of 606 gave a general stimulus to e use of germicidal preparations in pyogenic fections. The use of perchloride of mercury was introduced, but its place was soon taken by less xic mercurial compounds such as the salicylate, d especially mercurochrome. In this substance the agulative property of mercurial salts is greatly duced, whereas penetration is aided by the introction of the aniline dye fluorescein. Though far om being an ideal blood antiseptic, it is perhaps e nearest approach to this that we at present ssess. The most sensitive tissue which it meets the course of its action is the kidney, and, since amage done to this organ is so apt to be permanent, e use of mercurochrome calls for the utmost care.

Specificity of Remedies.

Of late years we have seen a reaction against ne doctrine of specificity in the therapeusis of icrobic infections. This reaction has shown itself the field of bacteriotherapy and also in the field f chemotherapy. We have seen the introduction of rotein shock, and also of what not seldom—though his effect is perhaps not intended—results in chemical hock. Such treatments have their basis of reason the hypothesis that the mechanism of Immunity generic rather than particular, and that it may herefore be activated by the same stimulus though he disease be caused by quite different species of nfecting agents. Such a conception is fundamental, ut the evidence supporting it is at present too light to warrant its acceptance as a sound basis or a scheme of therapeusis in infective diseases enerally. As usual, it may possibly be found that he truth lies somewhere between the two extremes. f specificity and non-specificity. The supposition, or example, that a dose of staphylococcal antigen may so jostle the immunity mechanism—evidently a very elaborate affair—as to leave the patient somewhat better when a state of relative equilibrium is once more established, and that this may happen even when the infection is bacillary in origin: such supposition is not incompatible with the view that an additional, and perhaps more valuable, benefit is derived from such administration in cases in which the infection is homologous with the particular antigen used, in this case staphylococcal. Even the idea of a "provocative reaction" may not be so specific as is usually supposed. The danger lies in *assuming a simple interaction, or a single one, or a* direct one, when all the time it may be complex, multiple, and indirect. There can be no harm in exploiting these new remedies and these ideas to the full provided we keep an open mind as to the nature of the interaction, and, it may be added, provided we use forbearance in accepting the explanation that fits with our own preconceived ideas, and decline to consider other and alternative ideas.

But since we are dealing always with an organism which possesses defences of its own, it behoves us to be careful that our reputed remedies do not merely add to the load the patient has to carry, and thus put a drag upon his natural resistance to his disease. This is an age of hustle, and a lust for the royal road to recovery is everywhere apparent. We are prone to forget that, though we may hope to shorten the course of an infection by our intervention, the chance of our being able to substitute an entirely different set of interactions from those by which the tissues reassert their criterion of health is remote. I do not myself find it difficult to visualise a remedial agent which shall expedite the natural course of recovery from an infection. There would often appear to be a lag in this natural process which, quite conceivably, might be overcome by appropriate means. But this raises the question as to whether the patient possesses a reserve in his immunity mechanism which can be called up for our purpose. And it may well be that this is a matter varying considerably in different individuals.

We get hints of this being actually so. Though, like many other of their terms, the words "sthenic" and "asthenic," used by our teachers of some thirty years ago, lacked clear definition, they undoubtedly correspond with observed clinical pictures. And, as one man's meat is another man's poison, so, I suggest, the contents of a hypodermic syringe that are found to be tolerated, or even appreciated, by one patient, may be definitely harmful to another, and yet both may be stricken by the same infection. That a dose of X.Y.Z 42 "will often enable an influenza patient to resume work on the third day" (I quote the advertisement) is not a controvertible statement, because a lot of other remedial measures have exactly the same to their credit; and provided the attack is quite a mild one, these measures may not have included any drugs whatever. But that (to quote again) "there is definite clinical evidence that the effect of injecting X.Y.Z 42 in the early stages of influenza is to reduce by one-half the duration of the disease and its accompanying symptoms" is a matter which must be left to the members of this Society and other equally competent observers to decide, rather than to the makers of the drug.

Concerning another preparation which I will call Angelina (said to contain "specific antibody," which is exactly what it does not contain) in the treatment of pneumonia we read—and the popularity. It is only since the war that reliable and constant apparatus in X ray work have been developed. Accurate dosimetry, and especially the co-relation between physically measured and biological dosage, are, again, of quite recent development; so also is the technique for depth irradiation. It is clear, therefore, that the stage has only been set within the last few years for really accurate observations of the therapeutic value of X rays. A vast amount of ill-controlled work is being done in this sphere, and by practitioners who have not had the necessary training for the purpose. This cannot be in the public interest, and we welcome the institution of a diploma which, supposing it to be adequately safeguarded and of a high standard, will serve to guide the patient and his doctor in the direction of efficiency. As an example of inefficiency may be mentioned the treatment of carcinoma, other than surface lesions, by low voltages, the use of which, besides being ineffective, prejudices the approach for subsequent proper treatment. On the other hand, low voltages have their value in several other directions, and their limits of service, as in the case of high voltages, are still quite unknown.

In the case of radium, no less than in X rays, the technique of administration demands whole-time service. So specialised, indeed, has the work become in the case of these two therapeutic measures that it seems impracticable for the same person any longer to engage in both with any degree of efficiency. Nor is it likely that, in the case of X rays, the same person can, in the patient's best interest, undertake both their diagnostic and their therapeutic application.

The segregation of these two important methods of treatment must needs result in a certain lack of unanimity as to which of them is to be preferred in particular cases. The exponent of either method naturally tends to consider it the fitter of the two, since he gets better results with the familiar, than with the unfamiliar, technique. It therefore becomes a matter of considerable importance that the practitioner, who is directly responsible for the patient, should acquaint himself thoroughly with the possibilities of both methods, since his own judgment is likely to be called upon, more and more frequently, to decide which is the more likely to attain the result desired.

The recent boom in the treatment of inoperable—and in some instances of operable—neoplasms, led to a great demand for radium in this country. The demand was quickly met. It then became apparent that there were not enough trained workers to deal with the radium actually available, and we are to-day witnessing the anomaly of radium going abegging. This position will, however, adjust itself when, on the one hand, workers have become more expert and, on the other hand, when we have extended the list of diseases for which it is reasonable to try the remedy.

Meantime it is interesting to observe that a great deal more experience is required before even the experts are agreed as to the dosage, the frequency, and the field of irradiation, in the case both of radium and of X rays, and even in diseases for which both have been used as a routine method of treatment for several years. A good example of this fact is seen in leukæmia: are the best results obtained from large doses given infrequently, or from small doses given frequently, and should it be the spleen, or the bones, or the glands, or some neutral part or parts, or several of these, that should form the field of irradiation?

Serotherapy.

In the treatment of microbic infections we hav
seen the swing of the pendulum more than onc
between bacteriotherapy and chemotherapy. Th
introduction of the method of passive immunity b
means of antisera, and, later, of the method of acti
immunity by means of bacterial antigens, led to bi
hopes. In the latter instance, it must be admitte
it led to big business also. During 30 years' experi
ence of these methods there have been great di
appointments, and yet, here and there, stimulatin
successes. In the case of serum therapy it is possibl
by further research and trial along two direction
that some of the former hopes may be redeeme
(1) The first direction relates to the determination
different types of the infecting agent within a grou
and the preparation of type-sera for use in hom
logous infections. Efforts have already been ma
along this line in the case of the *pneumococcus* a
the meningococcus. In the even more important gro
of streptococci, though the difficulties are greater,
similar effort may yet be rewarded by good resul
(2) In a second direction hope springs afresh. It h
been held for a long time that the exotoxins produc
during culture were not of service in the preparati
of antisera in coccal infections. They were for t
most part carefully separated off from the bodies
the cocci, which alone were used for the immunisi
inoculations. The resulting serum was theref
described as bactericidal or bacteriolytic. It
been found more recently, however, that a mu
more potent serum results from the use of th
exotoxins together with the endotoxins. Th
newer exotoxin-sera are now on trial, and some
the results of their use, especially in acute and vi
lent infections by *Streptococcus pyogenes* (vel *hæm*
ticus), have been strikingly good. These sera, hav
been chiefly obtained by the use of streptococci fr
the throat in severe cases of scarlet fever, have b
somewhat unfortunately labelled "scarlatinal a
strep. sera." They are, however, quite as usefu
streptococcal infections other than in scarlet feve
they are in this disease itself.

Vaccines.

The "opsonic index" hypothesis gave a sembla
of reasonableness to vaccine therapy without wh
the early hopes entertained on its behalf wo
probably have dwindled much earlier. Now that
must regard the method as entirely empirical the
is free for fuller exploitation, and that it has certa
had in no small measure. But though we have sen
out to the tissues of the infected patient spe
antigen in divers ways—dead, living, "*detoxicat*
"sensitised"; as endoplasm, as ectoplasm; and
divers systems of dosage—minute doses frequentl
massive dose singly, and by all gradations and
various intervals; the very cases of infection
which we most need help seem to elude all t
processes. And yet it must be admitted that
and there the general methods at our disposal
combating pyogenic infection in individual c
seem to receive striking assistance from ant
therapy. To those of us who have formerly incl
strongly towards this method, consideration of
present position with regard to the treatment of
diseases as pulmonary tuberculosis, septic e
carditis, and staphylococcal pyæmia, for exan
must needs cause a feeling of discontent. For i
three of these diseases we rely to-day upon exa
those measures of a general, non-specific sort that
did a quarter of a century ago. *But here* agai

htheria were notified. In the $3\frac{2}{3}$ years (11 terms) lowing the immunisation of the school, the routine swabbing every throat was allowed to lapse; d only 345, out of the 834 cases of total sore-throats, re swabbed in this period; 19 cases of "official" phtheria were discovered, but of these only four re notified. Therefore there was nearly a tenfold duction in the incidence of *discovered* "official" phtheria after immunisation—from 50·7 to 5·2 ses per annum. But even these two rates are not irly comparable, because the criteria which are ed for classifying "official" diphtheria take notice of the clinical type of sore-throat. erefore when, as before immunisation, all sore-roats are taken, the morbidity of "official" phtheria equals the product of the morbidity from l sore-throats and the incidence of diphtheria cilli in sore-throats, which before immunisation as 22·2 ± 0·8 per cent., while in the same period the orbidity of sore-throats averaged 227 cases per nnum. The product of these two rates is 50·7—e morbidity of "official" diphtheria before the tive immunisation of G.H.S. The incidence of fection with diphtheria bacilli in those sore-throats hich were swabbed after immunisation was 5·5 ± 0·8 er cent., and since the total sore-throat morbidity uring the same period was 228 per annum, the roduct of these two rates would be 12·5. Supposing, herefore, the 345 throats which were examined ad been selected at random, then the number of "official" diphtheria cases, more than half of which ould not have been discovered, should have been 2·5 per year instead of the 5·2 which were actually iscovered. The fall in the morbidity of "official" iphtheria after immunisation would then have been nly fourfold—from 50·7 to 12·5 cases per year. One ay note in passing that the average yearly morbidity f total sore-throats, including diphtheria, was equal n both periods. Therefore the morbidity of sore-hroats, excluding "official" diphtheria, was greater fter immunisation by about 38 cases per year.

Of course, in practice, unless all sore-throats are taken, those which are examined for diphtheria bacilli are always subject to a greater or less degree of selection. However, at G.H.S. after immunisation the large majority of sore-throats were examined more out of curiosity than with any idea that they resembled clinical diphtheria, though, of course, any that were clinically suggestive of diphtheria were specially selected. Nevertheless, seeing there was practically no *clinical* diphtheria at this time, and considering the large fraction of all throats which were swabbed, their selection must have been nearly at random. Hence, if after, as before, the immunisation of the school, all sore-throats had been bacteriologically examined, the incidence of "official" diphtheria would have been nearer 12·5 than the 5·2 cases per annum which were discovered.

ESTIMATED "REAL" DIPHTHERIA.

If it is allowed that diphtheria carriers can acquire on-diphtheritic infections of the throat, or that ordinary sore-throat patients can become diphtheria carriers, then it is obvious that a certain proportion of "official" diphtheria is not "real." It is also evident that the higher the morbidity of non-diphtheritic sore-throat, and the higher the diphtheria carrier-rate, the greater will be the error in diagnosis, when diphtheria is notified on the "official" criteria (non-diphtheritic" = not in any sense due to *C. diphtheriæ*).

For the sake of illustration it is assumed non-diphtheritic sore-throats and diphtheria carriers are distributed independently and at random in a community, then, the carrier-rate being known, the proportions of "real" and "carrier cases" in a random collection of "official" diphtheria patients can be calculated. For example, during the $6\frac{1}{3}$ years prior to immunisation, the frequency of symptomless infection with *C. diphtheriæ* among 4827 healthy boys was 6·1 ± 0·2 per cent. Therefore, on the above assumption, the 319 "official" cases of diphtheria, which were collected at a time when all sore-throats were swabbed, consisted of 254 cases of "real" diphtheria and 65 carriers who had a coincident sore-throat. (Let x=number of "real" and y=number of "carrier" cases; then $x+y=319$ and $6{\cdot}1\,(1439-x)=100\,y$; whence $x=254$ and $y=65$.) Similarly, the healthy carrier-rate after immunisation averaged 3·7 ± 0·2 per cent. (3052 swabs); whence, with the additional assumption that the sore-throats were selected at random for swabbing, out of the 19 "official" cases which were discovered, only seven cases of "real" diphtheria would have been expected. According to these calculations, the estimated incidence of "real" diphtheria before and after immunisation was respectively 40·0 and 1·9 cases per annum; and the percentage of "real" diphtheria among the swabbed sore-throats was 17·6 ± 0·8 and 2·2 ± 0·5, but among all sore-throats these frequencies would have been 17·6 and 0·8 per cent., if we assumed that all the "real" cases of diphtheria would have been selected for swabbing. It is possible, if not probable, that "commensal" or carrier infections with *C. diphtheriæ* are more frequent in the subjects of non-diphtheritic sore-throats than in healthy individuals. If such is the case, then, other things being equal, the frequency of "real" among "official" cases of diphtheria would be even less than is suggested above.

THE DIAGNOSTIC ERROR IN "NOTIFIED" DIPHTHERIA.

The 20 per cent. error in the diagnosis of diphtheria, as estimated in the last section, is more than confirmed by clinical diagnosis. In 1921 and 1922 we ourselves considered that, of 127 cases of "notified" and "official" diphtheria, 38 (30 ± 3 per cent.) were not diagnosable on clinical grounds only. This result was independently confirmed in 1925 to 1927, when, in answer to our inquiry, Dr. T. H. Woodfield, superintendent of the Brook Fever Hospital, most kindly took the trouble to look up his sick records, and informed us that 34 (41 ± 3·6 per cent.) of 83 G.H.S. "official" cases sent to his hospital were, in his opinion, "not clinically recognisable as diphtheria." During this period, however, the ratio of avirulent diphtheria bacilli was exceptionally high, and the type of "recognisable" diphtheria was considerably milder than in 1921. More evidence of the extent of the diagnostic error in the notification returns of diphtheria is supplied by Caiger and O'Brien,[3] who found 41·7 ± 1·3 per cent. of patients, notified as diphtheria and sent to the London fever hospitals, were not clinically, or even bacteriologically, diphtheria. As at G.H.S., these experts found if a case was clinically "positive" that, for practical purposes, it also was always bacteriologically "positive." But, contrary to our experience, unless we have misunderstood their data, which is not very clear on this special point, the sore-throats in the fever hospital group, which were not clinically recognisable as diphtheria, were all "negative" on bacteriological examination. Since the diphtheria carrier-rate among the London County Council school-children is, and has been for-statement is italicised—that "recovery begins on the first day." The evidence given for this claim is that there is "a fall in the temperature six hours after each injection." But this, of course, is no necessary sign of betterment; it may be the converse. As to recovery beginning on the first day, it may be safely presumed that, in any infection, the patient begins to recover—or to die—on the first day. This is quite compatible with, indeed it is a direct inference from, all that we know about immunity.

The number of these substances that are to-day being used in combating infections is considerable, and increases almost weekly. They are for the most part complex bodies possessing very large molecules. Their use is by some based upon the hypothesis that the protective power of the plasma resides in a number of protein particles that circulate in this medium, and that these particles can be "condensed" or "dispersed" by the injection, intravenously or intramuscularly, of the chemical substances referred to. How much of this hypothesis is known, or understood, by the majority of those who employ these therapeutic agents is doubtful; perhaps such knowledge is not necessary; but the confidence of those of us who are as yet unconvinced of the efficacy of these remedies is not enhanced by the somewhat casual manner in which the typical devotee of this particular school speaks of his exploits: "I plugged him with X.Y.Z." . . . "I fired in Angelina." . . .

But given a little forbearance, and some commonsense, I think these remedies should by no means be condemned out of hand. What is more important, however, is that the physiologists should come to our rescue. Either there *are* particles in the blood plasma, or there are not; and, if there are, either they *are* "condensed" and they are "dispersed" by the injection of certain chemical substances, or they are not. I cannot find that anything is known with certainty about these fundamental things; and research into them seems urgently called for. At present the issue is confused, and perhaps the method is prejudiced, by the business enterprise of the manufacturer and by the ease with which he converts the busier and less sceptical members of the profession. If the syndicates who run these things really want to establish their remedies, let them set aside some of the money they are making to biological research. At present their extravagant claims have far outrun the flimsy basis of fact upon which they are based.

Progress of Therapeutics.

Medicine has been termed an "inexact science." And by some confusion of thought this old saw has by many been considered to represent a permanent state of affairs. But much in medicine that was inexact yesterday is exact to-day, and much that is inexact to-day will doubtless be exact to-morrow. And it is but to change the words rather than the facts if we say that what is empirical to-day will become rational to-morrow. In many things therapeusis lags behind pathology, but pathology should always be prepared to get an inspiration from therapeusis. It is right, because it is useful, that therapeusis should continue to push out its antennæ, in this and in that direction, hoping to feel new facts that even pathology has not found. These, if found, should be explored by pathology, so that the remedy chosen might have the three time-honoured cardinal merits for which every patient rightly pleads—it should cure safely, pleasantly, and swiftly.

ACTIVE IMMUNISATION AND DIPHTHERIA.

By Percival M. May, M.R.C.S. Eng.,
SURGEON-CAPTAIN, R.N. (RETD.); MEDICAL OFFICER TO THE ROYAL HOSPITAL SCHOOL, GREENWICH;

AND

Sheldon F. Dudley, M.D., M.R.C.P. Lond.,
SURGEON-CAPTAIN, R.N.; PROFESSOR OF HYGIENE IN THE ROYAL NAVAL MEDICAL SCHOOL, GREENWICH.

NEARLY three years ago we communicated t THE LANCET[1] a note on the active immunisatio against diphtheria of Greenwich Hospital Scho (G.H.S.). In this institution of 1000 boys the fa was recorded that the cases of diphtheria *which we* *notified* had decreased from about 5 per cent. p annum, before immunisation, to zero among th inoculated boys during the year after immunisatio In that paper we admitted that two cases "who throats suggested a diagnosis of diphtheria" we not notified, although virulent bacilli had be isolated from their throats; because we considere rightly or wrongly, that they were diphtheria carrie suffering from a coincident infection. At the tim Dr. E. W. Goodall[2] gently rebuked us for havi "decided not to recognise these cases as diphtheria because, as he justly said, "the slightest attempt gloss over a failure will lead to the discredit of t practice of immunisation." The reprimand w deserved, for the statistics from one point of vi were undoubtedly, though unintentionally, misleadi and form an instructive example of how would honest men are led by subconscious bias to overst their case.

For the specific purpose of comparing the incide of a disease before and after a certain event, it obvious, or should be, that the definitions of disease, and the criteria for diagnosis, must rem identical throughout the investigation, however mu the event in question may suggest that the modificat of definition or criterion is advisable.

"OFFICIAL" AND "REAL" DIPHTHERIA.

Before the immunisation of G.H.S. it had b customary, as elsewhere, to notify as diphth practically every patient who had a sore-throat which diphtheria bacilli could be demonstrated. order to simplify discussion, all cases which sat these two criteria, sore-throat and diphtheria bac will be classed as "official" diphtheria. Prior immunisation, "notified" and "official" diphth were identities—subsequently they were not. now "real" diphtheria is defined as any les caused by the toxins of *Corynebacterium diphthe* it is improbable that all cases of "official" diphth are "real." On the other hand, for practical purpo all "real" is also "official" diphtheria. Beca although a case, clinically diagnosible as diphth (which is of course notified), sometimes occurs which the bacteriological examination is negat yet such an event is far too rare, in a laborat accustomed to diphtheria work, for it to have effect on the subsequent argument.

During the 6⅓ years (19 terms) prior to ac immunisation, it was routine at G.H.S. to s every throat, irrespective of its clinical appeara or severity. In this period 1439 sore-throats (incl ing diphtheria) were examined. Diphtheria ba were found in 319. These cases of "offici phtheria were notified. In the 3$\frac{2}{3}$ years (11 terms) lowing the immunisation of the school. the routine swabbing every throat was allowed to lapse; d only 345, out of the 834 cases of total sore-throats, re swabbed in this period; 19 cases of "official" phtheria were discovered, but of these only four re notified. Therefore there was nearly a tenfold duction in the incidence of *discovered* "official" phtheria after immunisation—from 50·7 to 5·2 ses per annum. But even these two rates are not irly comparable, because the criteria which are ed for classifying "official" diphtheria take o notice of the clinical type of sore-throat. erefore when, as before immunisation, all sore-roats are taken, the morbidity of "official" phtheria equals the product of the morbidity from l sore-throats and the incidence of diphtheria acilli in sore-throats, which before immunisation as 22·2±0·8 per cent., while in the same period the orbidity of sore-throats averaged 227 cases per nnum. The product of these two rates is 50·7—e morbidity of "official" diphtheria before the tive immunisation of G.H.S. The incidence of fection with diphtheria bacilli in those sore-throats hich were swabbed after immunisation was 5·5±0·8 er cent., and since the total sore-throat morbidity uring the same period was 228 per annum, the roduct of these two rates would be 12·5. Supposing, herefore, the 345 throats which were examined ad been selected at random, then the number of official" diphtheria cases, more than half of which ould not have been discovered, should have been 2·5 per year instead of the 5·2 which were actually iscovered. The fall in the morbidity of "official" iphtheria after immunisation would then have been nly *fourfold*—from 50·7 to 12·5 cases per year. One ay note in passing that the average yearly morbidity f total sore-throats, including diphtheria. was equal n both periods. Therefore the morbidity of sore-hroats, excluding "official" diphtheria, was greater fter immunisation by about 38 cases per year.

Of course, in practice, unless all sore-throats are taken, those which are examined for diphtheria bacilli are always subject to a greater or less degree of selection. However, at G.H.S. after immunisation the large majority of sore-throats were examined more out of curiosity than with any idea that they resembled clinical diphtheria, though, of course, any that were clinically suggestive of diphtheria were specially selected. Nevertheless, seeing there was practically no *clinical* diphtheria at this time, and considering the large fraction of all throats which were swabbed, their selection must have been nearly at random. Hence, if after, as before, the immunisation of the school, all sore-throats had been bacteriologically examined, the incidence of "official" diphtheria would have been nearer 12·5 than the 5·2 cases per annum which were discovered.

ESTIMATED "REAL" DIPHTHERIA.

If it is allowed that diphtheria carriers can acquire non-diphtheritic infections of the throat, or that ordinary sore-throat patients can become diphtheria carriers, then it is obvious that a certain proportion of "official" diphtheria is not "real." It is also evident that the higher the morbidity of non-diphtheritic sore-throat, and the higher the diphtheria carrier-rate, the greater will be the error in diagnosis, when diphtheria is notified on the "official" criteria (non-diphtheritic" = not in any sense due to *C. diphtheriæ*).

For the sake of illustration it is assumed non-diphtheritic sore-throats and diphtheria carriers are distributed independently and at random in a community, then, the carrier-rate being known, the proportions of "real" and "carrier cases" in a random collection of "official" diphtheria patients can be calculated. For example, during the 6$\frac{1}{2}$ years prior to immunisation, the frequency of symptomless infection with *C. diphtheriæ* among 4827 healthy boys was 6·1±0·2 per cent. Therefore, on the above assumption, the 319 "official" cases of diphtheria, which were collected at a time when all sore-throats were swabbed, consisted of 254 cases of "real" diphtheria and 65 carriers who had a coincident sore-throat. (Let x=number of "real" and y=number of "carrier" cases; then $x+y=319$ and $6{\cdot}1\,(1439-x)=100\,y$; whence $x=254$ and $y=65$.) Similarly, the healthy carrier-rate after immunisation averaged 3·7±0·2 per cent. (3052 swabs); whence, with the additional assumption that the sore-throats were selected at random for swabbing, out of the 19 "official" cases which were discovered, only seven cases of "real" diphtheria would have been expected. According to these calculations, the estimated incidence of "real" diphtheria before and after immunisation was respectively 40·0 and 1·9 cases per annum; and the percentage of "real" diphtheria among the swabbed sore-throats was 17·6±0·8 and 2·2±0·5, but among all sore-throats these frequencies would have been 17·6 and 0·8 per cent., if we assumed that all the "real" cases of diphtheria would have been selected for swabbing. It is possible, if not probable, that "commensal" or carrier infections with *C. diphtheriæ* are more frequent in the subjects of non-diphtheritic sore-throats than in healthy individuals. If such is the case, then, other things being equal, the frequency of "real" among "official" cases of diphtheria would be even less than is suggested above.

THE DIAGNOSTIC ERROR IN "NOTIFIED" DIPHTHERIA.

The 20 per cent. error in the diagnosis of diphtheria, as estimated in the last section, is more than confirmed by clinical diagnosis. In 1921 and 1922 we ourselves considered that, of 127 cases of "notified" and "official" diphtheria, 38 (30±3 per cent.) were not diagnosable on clinical grounds only. This result was independently confirmed in 1925 to 1927, when, in answer to our inquiry, Dr. T. H. Woodfield, superintendent of the Brook Fever Hospital, most kindly took the trouble to look up his sick records, and informed us that 34 (41±3·6 per cent.) of 83 G.H.S. "official" cases sent to his hospital were, in his opinion, "not clinically recognisable as diphtheria." During this period, however, the ratio of avirulent diphtheria bacilli was exceptionally high, and the type of "recognisable" diphtheria was considerably milder than in 1921. More evidence of the extent of the diagnostic error in the notification returns of diphtheria is supplied by Caiger and O'Brien,[3] who found 41·7±1·3 per cent. of patients, notified as diphtheria and sent to the London fever hospitals, were not clinically, or even bacteriologically, diphtheria. As at G.H.S., these experts found if a case was clinically "positive" that, for practical purposes, it also was always bacteriologically "positive." But, contrary to our experience. unless we have misunderstood their data, which is not very clear on this special point, the sore-throats in the fever hospital group, which were not clinically recognisable as diphtheria, were all "negative" on bacteriological examination. Since the diphtheria carrier-rate among the London County Council school-children is, and has been for statement is italicised—that "recovery begins on the first day." The evidence given for this claim is that there is "a fall in the temperature six hours after each injection." But this, of course, is no necessary sign of betterment; it may be the converse. As to recovery beginning on the first day, it may be safely presumed that, in any infection, the patient begins to recover—or to die—on the first day. This is quite compatible with, indeed it is a direct inference from, all that we know about immunity.

The number of these substances that are to-day being used in combating infections is considerable, and increases almost weekly. They are for the most part complex bodies possessing very large molecules. Their use is by some based upon the hypothesis that the protective power of the plasma resides in a number of protein particles that circulate in this medium, and that these particles can be "condensed" or "dispersed" by the injection, intravenously or intramuscularly, of the chemical substances referred to. How much of this hypothesis is known, or understood, by the majority of those who employ these therapeutic agents is doubtful; perhaps such knowledge is not necessary; but the confidence of those of us who are as yet unconvinced of the efficacy of these remedies is not enhanced by the somewhat casual manner in which the typical devotee of this particular school speaks of his exploits: "I plugged him with X.Y.Z." . . . "I fired in Angelina." . . .

But given a little forbearance, and some commonsense, I think these remedies should by no means be condemned out of hand. What is more important, however, is that the physiologists should come to our rescue. Either there *are* particles in the blood plasma, or there are not; and, if there are, either they *are* "condensed" and they are "dispersed" by the injection of certain chemical substances, or they are not. I cannot find that anything is known with certainty about these fundamental things; and research into them seems urgently called for. At present the issue is confused, and perhaps the method is prejudiced, by the business enterprise of the manufacturer and by the ease with which he converts the busier and less sceptical members of the profession. If the syndicates who run these things really want to establish their remedies, let them set aside some of the money they are making to biological research. At present their extravagant claims have far outrun the flimsy basis of fact upon which they are based.

Progress of Therapeutics.

Medicine has been termed an "inexact science." And by some confusion of thought this old saw has by many been considered to represent a permanent state of affairs. But much in medicine that was inexact yesterday is exact to-day, and much that is inexact to-day will doubtless be exact to-morrow. And it is but to change the words rather than the facts if we say that what is empirical to-day will become rational to-morrow. In many things therapeusis lags behind pathology, but pathology should always be prepared to get an inspiration from therapeusis. It is right, because it is useful, that therapeusis should continue to push out its antennæ, in this and in that direction, hoping to feel new facts that even pathology has not found. These, if found, should be explored by pathology, so that the remedy chosen might have the three time-honoured cardinal merits for which every patient rightly pleads—it should cure safely, pleasantly, and swiftly.

ACTIVE IMMUNISATION AND DIPHTHERIA.

By Percival M. May, M.R.C.S. Eng.,
SURGEON-CAPTAIN, R.N. (RETD.); MEDICAL OFFICER TO THE ROYAL HOSPITAL SCHOOL, GREENWICH;

AND

Sheldon F. Dudley, M.D., M.R.C.P. Lond.,
SURGEON-CAPTAIN, R.N.; PROFESSOR OF HYGIENE IN THE ROYAL NAVAL MEDICAL SCHOOL, GREENWICH.

Nearly three years ago we communicated to The Lancet[1] a note on the active immunisation against diphtheria of Greenwich Hospital School (G.H.S.). In this institution of 1000 boys the fact was recorded that the cases of diphtheria *which were notified* had decreased from about 5 per cent. per annum, before immunisation, to zero among the inoculated boys during the year after immunisation In that paper we admitted that two cases "*whose throats suggested a diagnosis of diphtheria*" were not notified, although virulent bacilli had been isolated from their throats; because we considered, rightly or wrongly, that they were diphtheria carriers suffering from a coincident infection. At the time, Dr. E. W. Goodall[2] gently rebuked us for having "decided not to recognise these cases as diphtheria," because, as he justly said, "the slightest attempt t gloss over a failure will lead to the discredit of th practice of immunisation." The reprimand wa deserved, for the statistics from one point of vie were undoubtedly, though unintentionally, misleading and form an instructive example of how would-b honest men are led by subconscious bias to overstat their case.

For the specific purpose of comparing the inciden of a disease before and after a certain event, it obvious, or should be, that the definitions of t disease, and the criteria for diagnosis, must remai identical throughout the investigation, however muc the event in question may suggest that the modificati of definition or criterion is advisable.

"OFFICIAL" AND "REAL" DIPHTHERIA.

Before the immunisation of G.H.S. it had be customary, as elsewhere, to notify as diphther practically every patient who had a sore-throat which diphtheria bacilli could be demonstrated. order to simplify discussion, all cases which satis these two criteria. sore-throat and diphtheria bacil will be classed as "official" diphtheria. Prior immunisation, "notified" and "official" diphther were identities—subsequently they were not. now "real" diphtheria is defined as any lesi caused by the toxins of *Corynebacterium diphtheri* it is improbable that all cases of "official" diphther are "real." On the other hand, for practical purpos all "real" is also "official" diphtheria. Becau although a case, clinically diagnosible as diphthe (which is of course notified), sometimes occurs which the bacteriological examination is negati yet such an event is far too rare, in a laborato accustomed to diphtheria work, for it to have a effect on the subsequent argument.

During the $6\frac{1}{3}$ years (19 terms) prior to acti immunisation, it was routine at G.H.S. to sw every throat, irrespective of its clinical appearan or severity. In this period 1439 sore-throats (inclu ing diphtheria) were examined. Diphtheria bac were found in 319. These cases of "officia s negative. These three boys probably represent mildest type of "real" diphtheria patients, o respond rapidly to infection by becoming Schick nune, in contrast to clinically recognisable cases, h as A and B, who, as a rule, remain Schick ceptible after their recovery.

. *diphtheriæ* was isolated from 10 of these 15 cases, l nine of the cultures were toxigenic. This pre- minance of virulent cultures cannot be used as an gument that most of this group were cases rather in carriers. Because, although a few carriers of irulent diphtheria bacilli were discovered when abbing boys on entry, yet Case 6 was the only boy io had been more than a term at G.H.S. from which avirulent culture of *C. diphtheriæ* was obtained er September, 1929. Between this date and July, 31, 23 consecutive cultures of *C. diphtheriæ* isolated m the throat swabs of healthy boys were all xigenic.

Of the 13 negative Schick reactors (including case D) io got "official" diphtheria, eight (61 ± 8 per nt.) were originally Schick susceptible on entry, it had been "artificially" made Schick immune fore contracting their sore-throats. The other e were "naturally" Schick immune on entry. fty-seven per cent. of all the boys who joined G.H.S. ter the school had been immunised had positive hick reactions on entry. Therefore there was tle evidence as to whether "natural" or "artificial" hick immunes were the more susceptible to "official" phtheria.

As a group, the 15 cases of "official" diphtheria, hich were not notified, had no outstanding clinical haracteristics to distinguish them from those patients i whose sore-throats *C. diphtheriæ* could not be emonstrated. Hence, because no one can say for ertain whether or not any *individual* case of "official" iphtheria, which is not clinically diagnosable, is aused by the toxins of *C. diphtheriæ*, the question ay appear to be an academic quibble of no practical mportance. Nevertheless, the *group* phenomena, discussed in this paper, support the hypothesis hat many, if not the majority, of such cases of 'official" diphtheria are subjects whose coincident nfection with *C. diphtheriæ* has no ætiological relation with their sore-throat; while the remainder are very mild, but "real" diphtheria cases in subjects who are partially immune. If this hypothesis is true we are aced in practice with more or less of an impasse; because the majority of diphtheria cases will always be missed, unless the majority of all types of sore-throat are swabbed, irrespective of their clinical character. Or, put in another way, because, apart rom the text-book case, one type of sore-throat suggests diphtheria as much as another. This does not only apply to an institution such as G.H.S., because diphtheria carrier-rates, and sore-throat morbidities as high as those reported in this school, are by no means infrequent outside it.

INDIRECT EFFECT OF ACTIVE IMMUNISATION ON NOTIFICATION.

The experience of active immunisation at G.H.S. forces home the practical lesson that, provided a case is known to have an undoubted Schick negative reaction (not merely to have had a prophylactic course of inoculations), the throat swab can be discarded, and such sore-throats diagnosed and treated on their clinical face value. Thus, active immunisation by an indirect psychological action reduces the number of diphtheria notifications in two ways. First, the confidence produced by the knowledge the patient and all his contacts are Schick immune, prevents the physician from notifying any type of sore-throat as diphtheria, and sending him to a fever hospital merely on the safety-first principle. Thus the positive error in diagnosis is diminished. Secondly, the mild, indefinite, and transitory cases of "real" diphtheria, which admittedly sometimes occur in Schick immunes, will often be "missed" if the throat swab is not regularly used, or, if it is used, such cases may be classed wrongly as "diphtheria carriers with coincident sore-throats." In this way the negative error in diagnosis is increased. These were the indirect effects of active immunisation which Dr. Goodall[2] spotted in our first communication. We have tried hard this time to eliminate our conscious prejudice in favour of active immunisation, but of course we cannot remove any fraction of bias which may remain buried in our subconscious minds.

CONCLUSION.

To summarise, the extent of the reductions in diphtheria-rates which were observed in the 3⅔ years following, as compared with the 6⅓ years preceding, the active immunisation of G.H.S. are as follows:—

Notifications of diphtheria per annum	46	times	less.
Estimated "real" cases of diphtheria per annum	21	,,	,,
Discovered "official" cases of diphtheria per *annum*	9·8	,,	,,
Frequency of *C. diphtheriæ* in sore-throats ..	4·0	,,	,,
,, ,, ,, ,, in healthy boys ..	1·6	,,	,,
Morbidity of all sore-throats per annum ..	equal.		

We personally believe that the most important cause of all the above reductions was the immunisation of the school; but we expect that many medical men will prefer to adhere to what is perhaps the "common sense" view, that, for practical purposes, "KLB positive" plus a "sore-throat"—i.e., our "official" diphtheria is always "real" diphtheria (see definition in section 2). If we accept this hypothesis, we will have to admit that the continued maintenance of Schick immunity in 97 per cent. of the inhabitants of G.H.S. was, with certainty, only followed by a fourfold reduction in the incidence of "common sense" diphtheria. Nevertheless, even had no change taken place in the "clinical severity," or duration of the disease, this reduction was more than worth while from any point of view—medical, financial, or educational. But in our opinion (which of course must be biased), if the morbidity of diphtheria is only granted a fourfold reduction, the "clinical severity," which then becomes relatively far more important than morbidity, must have declined at least a hundredfold after active immunisation.

Our thanks are due to Surgeon-Commander T. C. Patterson, R.N., who, after February, 1930, was responsible for the technical immunology and bacteriology at G.H.S. Also to Dr. R. A. O'Brien, of the Wellcome Research Laboratories, who supplied the prophylactic agents used in G.H.S.

Waking Hour of Hospital Patients.—The central public health committee of the London County Council have decided that, save in special circumstances, no patient in the Council's hospitals is to be awakened earlier than 6 A.M. Where, owing to insufficiency of staff, this rule does not yet apply, it will be put into operation as soon as circumstances permit.

some years, approximately the same as the average rate in G.H.S. prior to immunisation, Caiger and O'Brien's paper, if we interpret it correctly, would suggest that a non-diphtheritic sore-throat in a diphtheria carrier must be rare. This discrepancy between the "official" cases at G.H.S. and the "notified" cases which were sent to the London fever hospitals is perhaps caused by the excessive number of ordinary sore-throats which were swabbed at G.H.S.

In any event it is very evident, provided the error in the diagnosis of notified diphtheria is as high as the fever specialists think, that even if active immunisation should ever prove successful in completely eradicating "real" diphtheria from a community, it could not effect the 40 per cent. of false notifications. However, that part of the error in diagnosis, caused by notifying carriers with non-specific throats, would diminish if the carrier-rate is reduced as a result of active immunisation. One may note here that, although the average carrier-rate at G.H.S. fell after the immunisation of the school, yet the fall was largely caused by the disappearance of avirulent *C. diphtheriæ*. Large carrier-rates are nevertheless compatible with a fully immunised population. More than two years after G.H.S. was fully immunised, a sample of 93 healthy boys, the inhabitants of one dormitory, were swabbed, and eight cultures of toxigenic *C. diphtheriæ* were isolated from among them—an 8·6±2 per cent. virulent carrier-rate in a sub-group, all but one or two of whose members had negative Schick reactions. The fever specialists have demonstrated how the official notifications of diphtheria must form an inadequate index on which to judge the effect of any prophylactic scheme directed against diphtheria. It would seem that a better index would be the frequency of false clinical diagnoses among the cases sent to the fever hospitals as diphtheria. When this frequency approached 100 per cent. we could feel certain the preventive measure was a success.

It is a curious paradox that the more careful a physician is to exclude (*sic*) diphtheria by swabbing sore-throats which are not clinically diagnosable, the greater may be his error in diagnosis, though he will, of course, miss fewer cases of "real" diphtheria.

DIPHTHERIA IN SCHICK IMMUNES.

The high degree of immunity to severe clinical diphtheria which is exhibited by Schick immunes has been discussed elsewhere.[4] Suffice it to say that Park,[5] whose experience is unrivalled, says he has never seen an undoubted case of diphtheria in a subject possessing an undoubted negative Schick reaction; and our limited experience at G.H.S. is in agreement with this dictum, as the subjoined Table of the 19 "official" diphtheria cases which were discovered after the immunisation of G.H.S. shows. In this table the four "definite" cases, which were the only ones notified, are lettered A to D. A, B, and C were new entries who contracted diphtheria before being inoculated. A and B had positive Schick tests which remained positive after their return to school until they were artificially immunised. Case C was sent to hospital with jaundice before he was Schick tested, and developed diphtheria while in hospital. On his return to G.H.S. his Schick test and throat swab were both negative. Case D deserves special mention as the only boy with a negative Schick test who was notified as diphtheria.

This patient reported sick on March 8th, 1931, with an indefinite sore-throat. On March 10th there was a large greyish patch of membranous exudation on the right tonsil. Temperature was 100·4° F. He was sent to the fever hospital, and virulent bacilli were recovered from a throat swab taken at G.H.S. He was perhaps not an undoubted case of diphtheria, but he was the negative Schick reactor who most resembled it. Moreover, this subject had had four consecutive positive Schick tests, and five inoculations of full strength toxoid, before his fifth Schick test in October, 1930, was negative, about eight months after his joining school, and five months prior to the onset of symptoms. His Schick test, on return from hospital in May, 1931, was still negative.

With three doses of the diphtheria antigen as used on this case over 95 per cent. of any natural group of Schick susceptibles should acquire Schick immunity within three months, which suggests such subjects as Case D, who are exceptionally refractory to artificial active immunisation, are especially susceptible to clinical diphtheria.

Table of "Official" Diphtheria Cases Discovered after the Active Immunisation of G.H.S.

Case reference.	Date of onset of sore-throat.	Months at school before illness.	Schick test on entry.	Prophylactic inoculations.	Last Schick test before illness.	Virulent (V) or Avirulent (A) *C. diphtheriæ.*	Clinical diagnosis of diphtheria.

? = "unknown"; def. = definite; neg. = negative.

We will now consider the 15 "official" cases
diphtheria, but which were neither notified n
recorded as diphtheria in the school records. Eig
of these patients have been classed as having
"indefinite" clinical diagnosis. On clinical groun
only, the probability of their being "real" diphthe
was small, unless a large proportion of the 326 so
throats, in which the swab was negative, were al
diphtheria. The remaining seven cases, labell
"negative," had injected catarrhal sore-throats a
no sign of any membranous exudation. They we
less like diphtheria than dozens of other patie
who had "negative" throat swabs. None of th
15 boys were really ill, and in all cases the sympto
cleared up in a day or two. They were, howev
kept under observation till their throat swabs w
"negative." Cases 9, 11, and 13 "carried" virule
bacilli for over two months. It was the invaria
rule at G.H.S. that any case which had more th
trivial symptoms, suspicious of diphtheria, was gi
antitoxin without awaiting the laboratory repo
Only Case 1 in this group received any diphthe
antitoxin, which is perhaps the best indication of th
clinical resemblance to diphtheria. Cases 4, 9, and
got "official" diphtheria during their prophylac
course. Their Schick reactions were positive 1,
and 21 days respectively before the onset of th
sore-throats. In each case another Schick te
about a month after the onset of the sore-thro

oming a career in itself. Treatment of this dition is difficult, as the patient has usually been an apprehensive nature since early childhood. ifiscation of the thermometer and an attempt remove some of the more obvious fears by per-sion may help, but a change in the patients umstances which forces him to be more dependent his own efforts and resources may be more successful. Banister[2] has rightly emphasised the fact t the unduly ego-centric make poor patients as is these who may become the valetudinarian ld-lags" known to every sanatorium. This centration on self interferes with sleep and prevents patient from getting that mental and physical t which is so essential for recovery.

ver-compensation.—Among the defence mechan-s produced by fear of consumption none is more -reaching in its consequences than over-compensa-n. The presence of so serious and dangerous a ease is inacceptable to the mind of the patient, d, not content with the mere repression of the a, he sets himself an impossibly high standard of ysical prowess, as a result of which he may commit ts of bravado, such as drinking to excess, in order demonstrate to himself and others how far removed is from the lethargic milk-drinking consumptive. e tell-tale thermometer is ignored, and by recording false reading the patient sets out to deceive the ysician he is paying to aid his recovery. Many es are lost through the operation of this mechanism. though for disciplinary reasons some of these tients cannot be kept in an institution, the sana-rium physician has no cause to pride himself on always kicking out fellows who play the fool," r each one of these represents a failure of treatment. ver-compensation is more amenable to treatment an the anxiety state previously described, and in ost cases it is not difficult to give the patient insight to his mental condition, after which the need for er-compensation disappears. It is a more difficult atter however, to diagnose this mechanism as eception of the physician is part of the process.

Regression from and a failure to face reality is nother common phenomenon. In the early stages treatment few patients will admit to themselves at they have any doubt as to the favourable outcome f the disease, although as time goes on some will state hat all the time they have had an underlying fear hat they might never recover which is in sharp ontrast with their conscious belief that they will e able to lead perfectly normal lives after a few eeks or months of treatment. Similar reactions re brought into play when a patient who has had mple opportunities of studying the disease in others tarts a relapse. The symptoms that should give im clear warning are put down to trivial causes, ss of weight to errors of diet, fever to a chill, the eturn of sputum to a cold on the chest, and even a emoptysis to bleeding from the throat or nose. asked point blank if he did not know quite well at such symptoms indicated a return of the old ouble the patient may shrug his shoulders and say hat he supposes he knew underneath, but that e was so anxious not to be ill again that he did not let imself think about it.

Spes phthisica.—With unfavourable progress, this nderlying fear may reach such dimensions that the ight from reality, necessary to prevent it from forcing self into consciousness, reaches the extreme form nown as spes phthisica. This condition is similar n many ways to the mental state in early general paralysis, in which fear of the dreaded disease may drive the patient to the opposite extreme of arrogance and bombastic behaviour. It is difficult to know to what extent the phthisical patient succeeds in deluding himself; sometimes he seems to be fairly successful, but in other cases it is no more than a pitiful attempt at self-deception. The patient is

> Like one that on a lonesome road
> Doth walk in fear and dread
> And having once turned round, walks on,
> And turns no more his head;
> Because he knows a frightful fiend,
> Doth close behind him tread.

Projection is another phenomenon which is commonly observed in the tuberculous patient; it appears in the form of a morbid interest in other people's disease. The majority of sanatorium patients think nearly all the others are worse than themselves, and not a few derive consolation from the worse plight of the more severe case. Such a patient puts the blame, if he fails to improve, on doctors, climate, food, in fact on anything but himself.

The rebel type.—When a person of this type of mentality gets tuberculosis he makes a difficult problem for the physician, as the attitude he adopts against authority makes him regard any unorthodox remedy as necessarily more efficacious than the methods of treatment generally accepted by the medical profession. It is among these unfortunates that the "persecuted" quack has his most happy hunting ground. A frank admission of the smallness of our knowledge and the magnitude of our ignorance may help to gain the confidence of such a patient; at worst it will rob him of his favourite theme that all doctors are humbugs who claim omniscience.

Hysterical conversion.—In addition to the forms of mental reaction to tubercle already discussed, which are present in some degree in the majority of patients, wider variations from the normal are sometimes met with; amongst these the conversion of the unacceptable fear into hysterical symptoms is the most important. In one case attacks of tachycardia associated with severe dyspnœa were found to be due to repression of the fear that on account of his tubercle the patient would be unable to return to his work at the end of three months; at all events the attacks suddenly ceased when the patient was made to realise that he must face the facts of his condition and build more hopes on the distant than on the near future. The complete psycho-analysis of the Freudian, although unrivalled for the scientific study of the unconscious, is not practicable in the majority of cases of tubercle, and is probably undesirable in more than a very small proportion, as symptoms of neurosis must be very severe to justify the risk of aggravating the tubercle by the strain of the analysis.

HOME AND SANATORIUM ENVIRONMENT.

This discussion of the mental aspects of tubercle would not be complete without some reference to the difference between the home and the sanatorium atmosphere. The disadvantage of the former is that the patient is constantly reminded of his physical inferiority by being surrounded by healthy and solicitous relatives. The anxiety of his family may suggest to him that he is worse than is actually the case; on the other hand it may drive him to prove by over-compensation that he is really quite well. Many patients, who require strict rest, find it impossible to allow themselves to be waited on by elderly or more physically feeble relatives. Although the sanatorium provides a more healthy atmosphere in these respects, it is common to find patients who do not easily adapt themselves to an institutional

THE MIND IN TUBERCLE.

BY ANDREW MORLAND, M.D., M.R.C.P. LOND.,
RESIDENT PHYSICIAN, MUNDESLEY SANATORIUM.

IN the treatment of tuberculosis, healthy living is all-important, other remedies being no more than adjuvants, and in themselves useless to stay the progress of the disease if the mode of life is unhealthy. Since the course of the illness is invariably long much depends on the condition of the patient's mind, which must be such as would enable him to make a consistent effort towards recovery. It seems at first sight that there should be no great difficulty in carrying out so simple a régime as that described in the dictum, rest, fresh air, and good food; none the less it is common knowledge that many people with tuberculosis have not the endurance to carry out this mode of life for a sufficient period, and a large proportion of them throw away their lives as the result of this failure to adapt themselves to a suitable environment.

If the tuberculosis physician could learn so to influence the minds of his patients that they acquired a proper attitude towards the disease, the greatest therapeutic advance of the century would have been achieved.

Sound therapy can only be based on a proper understanding of pathology, and it is therefore necessary in the first place to study as fully as possible the mental states observed in persons with tuberculous disease. This problem is a vast one, as people of every type of mental make-up are liable to fall victims to tubercle, and in the present state of knowledge it is possible to attempt only a somewhat sketchy review of the subject.

ÆTIOLOGY.

That the resistance to tubercle and other diseases may be lowered as the result of a severe psychic trauma has long been admitted. More recently much has been written concerning the psychological "flight into disease." It is certainly not uncommon to meet with patients, especially in tuberculous families, who show many of the symptoms of phthisis but in whom physical and radiological signs are consistently absent. It is probable that many of these are suffering from purely psychological phthisis. Groddeck in his delightfully stimulating book "The Unknown Self" elaborates the theory that the organism deliberately makes use of a germ to attain its own ends. Although the results of experimental and accidental inoculation make it impossible to accept this theory in its entirety, there is much truth in it, and few will dispute the modified statement that illness is likely to follow when all desire for life and health have gone. The importance of the mind in the ætiology of consumption was clearly recognised by the late Arthur Latham who said [1] in 1917:

> "The increase of tuberculosis during the war could not be explained by increased infectivity, but could be explained by the increased strain and stress. We could only remove the disease by removing the strain and stress of working people; until this were done the result would be as unsatisfactory as at the present time."

In this connexion it is not out of place to point out that a strong case has been made for the psychic origin of such diseases as exophthalmic goitre and epilepsy which were long considered as purely organic.

Although, as has been said, any type of person may get tubercle, there does appear to be a particularly high incidence on those of outstanding intelligence, and the victims of the disease include a large number of men and women of genius. From this observation has arisen the idea that the toxin of tubercle stimulates creative capacity. This theory does not bear close examination, and it seems much more probable that the intensity of feeling and thought required for creative work, so often allied to an acute sensitiveness and vulnerability towards the inevitable harshness of a workaday world, make the genius a particularly easy victim to such a disease as tuberculosis. Dilke, shortly after the death of Keats, wrote: "Thought was intense with him and seemed at times to assume a reality that influenced his conduct and I have no doubt helped to wear him out." Such people have great difficulty in adapting themselves to their surroundings.

REACTION TO DIAGNOSIS.

It is a common observation that when the onset of tubercle is dramatic, for example by a profuse hæmoptysis, steady progress towards recovery is often made. With less conclusive proof of the presence of serious disease the attitude of the patient is apt to be incredulous; he shrinks from facing unpleasant facts, and will take any loophole for disputing the accuracy of the diagnosis. Medical men are the worst offenders in this respect, and I have met with arguments designed to prove that the acid-fast organism abundantly present in the sputum was not the tubercl bacillus. Even when convinced of the presence of th disease the majority of patients are outwardl confident that they will be quite well in three month or some equally unreasonable time. This attitud is in strange contrast with that of a man when one his friends is sent to a sanatorium, for in this case is usual to meet with a gloomy view, based on childhoo memories of the usual fate of "consumptives" ar on the excessively low rate of recovery from phthis in works of fiction. The opposite type of reaction which the patient shows extreme shock and fear also common, but tends to be of shorter durati and thus of less consequence. Interesting cases a met with in which both incredulity and terror a present, first one and then the other dominating t scene.

DURING TREATMENT.

The patient who shows a proper combination courage and caution, adaptability to a new enviro ment, and the capacity to form fresh interests when t old ones are inadvisable, has a good prospect recovery even when the disease is of moderate severi Unfortunately, it is only a small minority who a of this type from the start, but a considerable numb learn to adjust themselves after the first few months treatment.

There are many points of similarity between t tubercle and the war neuroses. Underlying both the fear of death and the resulting conditions m be looked on as the reactions of individuals of vary mental make-up to this all-pervading emoti The specialised form of slangy speech with which t soldier attempted to keep away his fears, is clos comparable to that of the tuberculosis patient w must refer to a refill as a "blow-up" and the repla ment of an oleothorax as "emptying the sump."

Anxiety.—Many patients are obviously appreh sive throughout the disease; unduly meticulous the conduct of their cure, they may record th temperatures almost hourly and regulate their li with stop-watch precision. Trivial symptoms treated with great seriousness and the self-cent condition, produced by the constant preoccupati with routine, results in the treatment of the dise oming a career in itself. Treatment of this dition is difficult, as the patient has usually been an apprehensive nature since early childhood. fiscation of the thermometer and an attempt remove some of the more obvious fears by persion may help, but a change in the patients umstances which forces him to be more dependent his own efforts and resources may be more successful.

THE MIND IN TUBERCLE.

BY ANDREW MORLAND, M.D., M.R.C.P. LOND.,
RESIDENT PHYSICIAN, MUNDESLEY SANATORIUM.

IN the treatment of tuberculosis, healthy living is all-important, other remedies being no more than adjuvants, and in themselves useless to stay the progress of the disease if the mode of life is unhealthy. Since the course of the illness is invariably long much depends on the condition of the patient's mind, which must be such as would enable him to make a consistent effort towards recovery. It seems at first sight that there should be no great difficulty in carrying out so simple a régime as that described in the dictum, rest, fresh air, and good food; none the less it is common knowledge that many people with tuberculosis have not the endurance to carry out this mode of life for a sufficient period, and a large proportion of them throw away their lives as the result of this failure to adapt themselves to a suitable environment.

If the tuberculosis physician could learn so to influence the minds of his patients that they acquired a proper attitude towards the disease, the greatest therapeutic advance of the century would have been achieved.

Sound therapy can only be based on a proper understanding of pathology, and it is therefore necessary in the first place to study as fully as possible the mental states observed in persons with tuberculous disease. This problem is a vast one, as people of every type of mental make-up are liable to fall victims to tubercle, and in the present state of knowledge it is possible to attempt only a somewhat sketchy review of the subject.

ÆTIOLOGY.

That the resistance to tubercle and other diseases may be lowered as the result of a severe psychic trauma has long been admitted. More recently much has been written concerning the psychological "flight into disease." It is certainly not uncommon to meet with patients, especially in tuberculous families, who show many of the symptoms of phthisis but in whom physical and radiological signs are consistently absent. It is probable that many of these are suffering from purely psychological phthisis. Groddeck in his delightfully stimulating book "The Unknown Self" elaborates the theory that the organism deliberately makes use of a germ to attain its own ends. Although the results of experimental and accidental inoculation make it impossible to accept this theory in its entirety, there is much truth in it, and few will dispute the modified statement that illness is likely to follow when all desire for life and health have gone. The importance of the mind in the ætiology of consumption was clearly recognised by the late Arthur Latham who said[1] in 1917:

> "The increase of tuberculosis during the war could not be explained by increased infectivity, but could be explained by the increased strain and stress. We could only remove the disease by removing the strain and stress of working people; until this were done the result would be as unsatisfactory as at the present time."

In this connexion it is not out of place to point out that a strong case has been made for the psychic origin of such diseases as exophthalmic goitre and epilepsy which were long considered as purely organic.

Although, as has been said, any type of person may get tubercle, there does appear to be a particularly high incidence on those of outstanding intelligence, and the victims of the disease include a large numb- of men and women of genius. From this observation has arisen the idea that the toxin of tubercle stimulates creative capacity. This theory does not bear close examination, and it seems much more probable that the intensity of feeling and thought required for creative work, so often allied to an acute sensitiveness and vulnerability towards the inevitable harshness of a workaday world, make the genius a particularly easy victim to such a disease as tuberculosis. Dilke, shortly after the death of Keats, wrote: "Thought was intense with him and seemed at times to assume a reality that influenced his conduct and I have no doubt helped to wear him out." Such people have great difficulty in adapting themselves to their surroundings.

REACTION TO DIAGNOSIS.

It is a common observation that when the onset of tubercle is dramatic, for example by a profuse hæmoptysis, steady progress towards recovery is often made. With less conclusive proof of the presence of serious disease the attitude of the patient is apt to be incredulous; he shrinks from facing unpleasant facts, and will take any loophole for disputing the accuracy of the diagnosis. Medical men are the worst offenders in this respect, and I have met with arguments designed to prove that the acid-fast organism abundantly present in the sputum was not the tubercle bacillus. Even when convinced of the presence of the disease the majority of patients are outwardly confident that they will be quite well in three months or some equally unreasonable time. This attitude is in strange contrast with that of a man when one of his friends is sent to a sanatorium, for in this case i is usual to meet with a gloomy view, based on childhoo memories of the usual fate of "consumptives" an on the excessively low rate of recovery from phthisi in works of fiction. The opposite type of reaction i which the patient shows extreme shock and fear i also common, but tends to be of shorter duratio and thus of less consequence. Interesting cases a met with in which both incredulity and terror a present, first one and then the other dominating th scene.

DURING TREATMENT.

The patient who shows a proper combination courage and caution, adaptability to a new environ ment, and the capacity to form fresh interests when th old ones are inadvisable, has a good prospect recovery even when the disease is of moderate severit Unfortunately, it is only a small minority who a of this type from the start, but a considerable numb learn to adjust themselves after the first few months treatment.

There are many points of similarity between t tubercle and the war neuroses. Underlying both the fear of death and the resulting conditions mu be looked on as the reactions of individuals of varyi mental make-up to this all-pervading emotio The specialised form of slangy speech with which t soldier attempted to keep away his fears, is close comparable to that of the tuberculosis patient w must refer to a refill as a "blow-up" and the replac ment of an oleothorax as "emptying the sump."

Anxiety.—Many patients are obviously apprehe sive throughout the disease; unduly meticulous the conduct of their cure, they may record th temperatures almost hourly and regulate their li with stop-watch precision. Trivial symptoms a treated with great seriousness and the self-centr condition, produced by the constant preoccupati with routine, results in the treatment of the disea stion of age in relation to improvement in both ances. The cases were for this purpose divided four groups: (1) Up to 29 years, (2) 30 to 39 rs, (3) 40 to 49 years, and (4) over 50 years. These ups were then considered as to whether they wed great improvement, improvement, slight rovement; no improvement, or deterioration. ing into account the smallness of the figures en so subdivided, no significant difference appears the various age-groups of either series. One refore came to the conclusion that age differences ween the two groups could justifiably be disarded.

---

[1] THE LANCET, 1917, ii., 792.

he duration of the disease was then considered. e cases in both series were divided into three ups as follows: (1) those with a history of under year; (2) those with a history of from one to years; (3) those with a history of over five years. ey were classified in the same manner as the age ups. In both series a slight drop in improvement s noted as the time since the onset of the disease gthened. This is a factor which has a bearing the comparison, as there were 50 per cent. of tients with a history of over five years in the nonccine treated and only 15 per cent. in the other oup.

The *condition on admission* was considered thirdly, d here again it is obvious that the series are not ogether alike. Unfortunately this particular was ly available in a proportion of the cases, so allowce has had to be made for the size of the figures. e results of this part of the inquiry are summarised Table III., which shows that 48 per cent. of the ccine treated cases were showing some degree of provement on admission, whereas in the nonccine treated the corresponding figure was only per cent.

TABLE I.—VACCINE-TREATED CASES.

CONDITION ON DISCHARGE.

The following symbols have been used throughout: ++ Great improvement, + Improvement, ± Slight improveent, 0 No improvement, — Worse.

	++	+	±	0	—	Total.	Total improved.
	106	159	40	25	1	331	305
er ent.	32	48	12	8	—	100	92

Table I. shows the condition of the 330 vaccinereated cases on discharge. It is seen that 92 per cent. ave made improvement of some degree or another. t is not intended to draw any conclusions from igures such as these, which may be so very greatly nfluenced by personal opinion, but they are included o furnish a possible comparison with the results of ther workers.

Table II.A shows the summary of the replies to he post-cards, and must be taken simply for what t is worth. It represents solely the patients' opinion f the progress made or of the course of the disease. nasmuch as other information, such as return to work nd so on, was often volunteered, it is not without alue, and is, in the circumstances, the only evidence f the sort that can be obtained. The degree of mprovement was not asked for, but was given in a umber of cases.

The list of patients that did not reply was examined, and it was found that the proportion that had improved, remained stationary, or got worse while in hospital was about the same as in the list which replied. It therefore seemed probable that the series under consideration represented a fair sample, and that its selection was not influenced by other factors than chance.

Table II.B shows the subsequent improvement in the 550 non-vaccine treated cases, the total admitting any degree of improvement being 43 per cent.

TABLE II.—SUBSEQUENT CONDITION.

A.—VACCINE TREATED.

	57	9	31	104	210	66
Per cent.	28	5	16	51	100	33

COMMENT ON THE DATA.

A comparison of these tables (II.A and II.B) shows that 61 per cent. of the vaccine-treated cases have made some degree of improvement, whereas in the non-vaccine treated group the total is only 43 per cent., a possible difference of 18 per cent. in favour of vaccine treatment.

If, however, this is considered with the figures showing the condition on admission (Table III.), it is seen that the difference is more apparent than real. As has been mentioned, 48 per cent. of the vaccine-treated patients stated that they were improving before admission, so that the absolute total improved was 61 per cent.—48 per cent.=13 per cent. In the non-vaccine treated 33 per cent. stated that they were improving before admission, so that in this case the absolute total was 43 per cent.—33 per cent.=10 per cent.

The real difference between the two series therefore seems to be represented by 13 per cent.—10 per cent. =3 per cent.—a difference which is not significant when taking into account the size of the figures. Even if there were a slight significant difference it is probable that it would be accounted for by the fact that the vaccine-treated cases had on the average a much shorter history. It is considered that the figures in Tables II. and III. are strictly comparable, atmosphere; although most of these settle down in a few days or weeks there are a few who cannot do so. It is interesting to note in this connexion that a recent example of this form of claustrophobia admitted that he had twice run away from school.

THE NEO-HIPPOCRATIC OUTLOOK.

The recent great advance in biochemical and physical knowledge has focused attention on that approach to the problems of disease by which all vital activity will ultimately be reduced to the interaction of various groups of atoms and electrons. Great as has been the gain of medical science and philosophy from this work, it has brought with it the danger that the reactions of the organism as a whole may be overlooked. Of all morbid conditions, tuberculosis is the one in which it is most essential to treat the patient rather than the disease. Specific remedies, although useful in many cases, are no more than adjuvants to general hygienic treatment aimed at "raising the resistance." In this struggle between health and disease the mind plays an important part, and I believe that further understanding of the mechanism by which the mind responds to the stimulus of the disease would enable more rational and effective treatment to be applied.

VACCINE TREATMENT IN INFECTIVE ARTHRITIS.

By Phyllis M. Congdon, M.D., Dipl. Bact. Manch.,
BACTERIOLOGIST TO THE DEVONSHIRE HOSPITAL, BUXTON.

Opinion on vaccine therapy in rheumatic diseases has for some time been in a state of flux. The theory of focal infection as an ætiological factor held out a promise from this form of treatment which few will now admit to have been entirely fulfilled. Nevertheless, there is a fairly substantial opinion that vaccine treatment is not without its value, and it seems therefore that a critical survey of a recent series may be of interest.

The literature of vaccine therapy in rheumatic diseases is in a most unsatisfactory condition, although reports of "good results" are not lacking. In many cases the numbers are inadequate, in others the diagnosis is vague or the number of unsuccessful cases is not stated, and the figures have rarely been considered with a view to determining how far any differences may be due to the factor of chance. The only way in which anything approaching proof can be obtained is to compare, in as many ways as possible, the results of treatment in two large series, in which the conditions are as much the same as may be.

It is desirable: (1) that the inquiry should be confined to one clinical entity; (2) that a control series of adequate size should be provided; (3) that every attempt should be made to minimise the personal factor; (4) that the intermittent character of the symptoms should be taken into account; and (5) that the factor of chance variation should be allowed for.

It must be admitted that only certain of these desiderata have been attainable. The inquiry has easily been limited to cases of infective arthritis only, and differences less than those possibly due to chance variation have been disregarded. The provision of a suitable control series has, however, been more difficult. The ideal method would of course have been to withhold all other forms of treatment from half the patients and to treat the other ha with vaccines. This, particularly on the large sca that would be necessary, is impossible. I have ha therefore, to be content with comparing two seri both treated in various ways, in one of which vaccin have been given. The series themselves are no identical, but where they differ an attempt has bee made to allow for the difference. The fact tha natural variations of symptoms tend to occur ha been partly dealt with by a consideration of th progress on returning home, and a comparison o this with the clinical condition of the patient o admission. Great care was taken that all case should be typical, and as there was no shortage o material, all doubtful cases were excluded.

The following criteria were used in the selectio of cases: (1) That the affection should have bee more or less continuous since its onset. (2) That should be polyarticular. (3) That at least one sm joint should be affected. (4) That the radiologi and laboratory findings, where present, should be agreement with the clinical diagnosis.

TECHNIQUE OF VACCINE THERAPY.

The stock vaccine was freshly prepared each y from about forty strains isolated from the teeth or from infective arthritis. The autogenous vacci were usually prepared from the same sources occasionally from other suspected foci.

The organisms were grown in 1 per cent. glucose nutr broth (pH 7·5) and produced a fairly abundant growt 24–48 hours. They we in 0·5 per cent. phenol i by heating in the wate standardisation by comparison with a tube containi 0·5 per cent. suspension of barium sulphate in w Sterility tests were made, and were left up for at least days before the vaccine was considered ready for use.

The vaccines were given subcutaneously just unde clavicle, at intervals usually of three or four days, sometimes weekly. The reaction was always allowe subside completely before giving another dose. The dose was as a rule in the neighbourhood of 5–10 mi The number of doses given to each patient was se more than twelve, and the average was eight. The pat in this, as in the non-vaccine treated group, receiv addition balneological and other forms of physical treat during their stay in hospital.

THE INQUIRY.

At the beginning of last year (1930) each pa who had received treatment in the period Jan 1928, to December, 1929, was requested to fill up return to the hospital a post-card stating whethe condition had (1) improved, (2) remained the s or (3) got worse, since returning home. No card was sent to a patient who had not been at l for at least three months. The majority had at home for very much longer, in fact for pe varying up to nearly two years. About 80 per of the cards were returned, and it was thus pos to get some idea of the late results of treatm at least from a subjective point of view.

It is well, in making a comparison of this des tion, to examine both series minutely with a to determining how nearly they are alike in particular except the essential one. As has mentioned, both groups of cases were treated in years 1928 and 1929, both received general t ment, and in both the sex distribution was rou about the same.

The *average age*, however, was definitely high the non-vaccine treated group, well over one- of the cases being over 50 years of age, where the other series this was the smallest group o It was therefore thought advisable to conside roof is, indeed, upon one who assumes a case to strate multiplicity of primary malignant tumours, there are so many possibilities of error in obser on and interpretation that one should approach subject with extreme reserve, and that only after fully considering the possibility of metastasis or lantation.

t is highly improbable that cases of multiple intra cal carcinomata can be explained away as examples netastasis, for. though epithelioma of the tongue ws an almost constant invasion of the lymphatic ids, secondary deposits elsewhere are extremely . Moreover, if these multiple tumours were the ilt of metastasis, we should expect to find secondary wths in other parts of the body as well.

ver 250 years ago, with only the knowledge and row views of his day, Tulpius, the Dutch anatomist, of the principal figures in Rembrandt's master e, "The Anatomist," said: "Cancer is just as con ious as inflammation of the eyes." Doubtless this in exaggerated statement, but there has accumu d much clinical and experimental proof that cancer ccasionally communicated from host to host or n one part of the body to another. Among the st striking examples are those showing the spread cancer of one side of the vulva to the other. n Bergmann[6] recorded a case of a man with a cer of the lower lip and exactly opposite to it on upper lip was a similar growth, and Macewen[7] s of a man with an epitheliomatous ulcer of his lip o had contracted the habit of rubbing the ulcer l then the tip of his nose with the same finger. enty months after the removal of the growth on lip, he returned with a large ulcer on the tip of the nose identical microscopically with the original tumour. Shimmelbusch[8] reported a similar case of apparent cancerous infection of the lip through the finger-nails of a person with an epithelioma of his ear.

There appears to be no doubt that implantation carcinoma of the mucosa of the alimentary canal has occurred on many occasions and that traumatised tissues are an especially fertile bed for this development. Hoche[9] has reported an epithelioma arising in the centre of a gastric ulcer in a patient with carcinoma of the œsophagus, and Dowden,[10] Challier,[11] among others, have described cases of implantation arising in colostomies from carcinoma of the large bowel. The development of carcinoma in the tooth-sockets in the case I have reported would seem without doubt to be another example of auto-inoculation or implantation and it would be illogical to invoke a different explanation of the origin of the carcinoma on the left tonsil in the same case. Probably many of the other cases of so-called multiple primary carcinomata of the buccal cavity are in reality examples of cancerous implantation.

CLINICAL AND LABORATORY NOTES

CASE OF ENTERO-MESENTERIC CYST

SIMULATING ACUTE RETENTION OF URINE

By H. J. Shorvon, M.R.C.S. Eng.,
E HOUSE PHYSICIAN, ST. OLAVE'S HOSPITAL, ROTHERHITHE;

AND

L. Wells, M.R.C.S. Eng.,
RESIDENT MEDICAL OFFICER, ST. OLAVE'S HOSPITAL.

ENTERO-MESENTERIC cysts often give the symptoms d signs of various acute abdominal conditions such acute appendicitis, intussusception, volvulus, or testinal obstruction, but we cannot find any record it simulating a case of acute retention of urine. e failure to pass urine, together with the presence a swelling in the abdomen having the shape and nsistency of a large palpable bladder but which at eration was found to be an intraperitoneal cyst, nder this case an unusually interesting one.

REPORT OF CASE.

Past history.—The mother stated that the boy had always een a delicate child and had often complained of tenderness the lower part of the abdomen, with vague abdominal mptoms. He had an attack of "catarrhal jaundice" hen aged 6, and 18 months ago was in bed for several onths with acute rheumatism. He was also admitted to spital in February, 1929, with a provisional diagnosis of testinal obstruction. The hospital notes of that time state at he had a history of continual vomiting of green fluid r a week with constipation. He appeared very ill, had a nken look on admission, with sordes on his lips. On xamination of the abdomen no peristalsis was observed, was doughy to palpation, no tumour was felt, but free uid was present. Paracentesis abdominis was performed and a straw-coloured fluid withdrawn. The pathological report stated that no tubercle bacilli were detected, cells were present, mainly small lymphocytes and endothelial cells. The culture was sterile. The constipation was treated, condition subsided, and patient was sent to a convalescent home some weeks later with a final diagnosis of tuberculous peritonitis. An interesting point bearing on his subsequent history was the fact that during his stay in hospital the patient had considerable difficulty in passing urine, and his foreskin was slit in an attempt to remedy this.

History of present attack.—The patient, now aged 8, was admitted to hospital on June 6th, 1931, with the diagnosis of acute retention of urine. A day before admission the boy returned from school in a collapsed state, was giddy, faint, and complained of pains in his abdomen. He was given an aperient and bowels were freely opened. He did not micturate that day, was very parched, drank freely, and was very restless during the night owing to the abdominal pain. He vomited that night and twice in the morning. On admission to hospital the patient was pale, thin, dull, and toxic, with a coated dry tongue. Temperature, 100·4° F.; pulse-rate, 100; respiration, 22. The abdomen was rigid, and a hard tender swelling was palpated in the mid-line reaching to half an inch below the umbilicus. There was free fluid in the flanks. The respiratory and central nervous systems were normal. A rubber catheter was passed without difficulty but no more than 4 ounces of urine was collected. Later another catheter was passed, but this time no urine came through. A catheter was passed under general anæsthesia in the theatre, but again no urine was withdrawn.

Operation.—A right paramedian incision was made. On opening the peritoneum free yellow fluid was found, and a large, fairly thin-walled intraperitoneal cyst was exposed. The cyst was the size and shape of a large coco-nut, was smooth, and had a pale greenish appearance. It was continuous with, and attached to the mesentery of the small intestine, near its fixation to the posterior abdominal wall, and was fairly mobile on its attachment. The attachment was broad with myxomatous appearance, and the small gut in one portion (about 1½ inches) was attached to it. The cyst was aspirated and some yellow fluid evacuated. It was then incised, and yellow jelly-like material was expressed. The inner lining of the cyst was very red and œdematous.

as both the statement as to condition on admission and the reply to the post-card represent the patient's point of view.

It is, of course, a fallacy that the post-cards were all sent out at the same time—that is, at greatly varying intervals after discharge, but as this was the same in both series the comparison still holds good. It was noted that there was no evidence of greater benefit in 92 patients who received autogenous vaccines than in the vaccine-treated group as a whole.

The conclusion is therefore that, within the limits of the inquiry, vaccines do not appear to hold out any better prospect of improvement or cure of infective arthritis than the other methods of treatment in use.

MULTIPLE MALIGNANT GROWTHS OF THE BUCCAL CAVITY.

By J. Bagot Oldham, M.B. Liverp., F.R.C.S. Eng.,
ASSISTANT HON. SURGEON TO THE NORTHERN HOSPITAL, LIVERPOOL; HON. SURGEON TO THE GENERAL HOSPITAL, BIRKENHEAD.

Lord Moynihan's clinical note on a Case of Primary Carcinoma developing, at intervals, in three different parts of the buccal cavity (The Lancet, Jan. 2nd) and his *statement that he has "never before seen two* primary malignant growths in the mouth" prompts me to report the following case.

On March 16th, 1931, a man, aged 62, was admitted into the David Lewis Northern Hospital, Liverpool. He complained that for three months he had been troubled by "soreness of his gums" on the left side. His mouth was edentulous and on the left side there was an epitheliomatous ulcer involving the floor of the mouth and the alveolus. The epithelioma was some two and a half inches long and extended back on to the fauces. The tongue could only be protruded half an inch beyond the gums and deviated to the left. The Wassermann reaction was negative. No involvement of the glands could be detected.

The growth was treated with surface application of radium on a plaque and when he was seen a month later the mouth seemed to be normal, the ulcer had healed up, and the induration of the floor of the mouth had gone. In July, however, he returned, complaining of severe pain in his left ear. On examination marked induration and thickening was found posteriorly in the angle between the tongue, the mandible, and the fauces. Radium was again applied. He returned for examination at intervals and appeared to be progressing well. The induration and the earache disappeared.

On Nov. 26th he came up for routine re-examination. He said he had come for his discharge as he had no pain and was sure he was cured. When I asked to see his mouth he protruded his tongue fully one and a half inches and deviated it well over to the right side so that I could examine the left side of his mouth. There was no sign of any recurrence of malignant disease on the left side. No glandular enlargement could be felt on the left side but, to my surprise, I found a hard mass of glands in the right submaxillary region and on the floor of the mouth, on the right side anteriorly, just under the tongue was the cause of this—a small indurated and ulcerated plaque, one centimetre in diameter. This plaque presented all the characteristics of an epithelioma. The patient was quite unconscious and even incredulous of this new development and at first refused to undergo further treatment. Later he consented to come into hospital and radium needles were inserted into the epithelioma and into the cervical glands.

In The Lancet of Oct. 26th, 1929, p. 873, I reported a case of Implantation of Epithelioma in the Alveoli of the Maxilla from primary growth in tongue which show similar features to Lord Moynihan's case. The main features of this case were as follows:—

A man aged 50 years. A very large epitheliomatous ulcer on right side of the tongue extending back on to right palato-glossal fold was excised with diathermy two weeks after the first and second right upper molars had been extracted. Ten weeks later he returned for re-examination and it was found that, though the tongue had completely healed and there was no sign of a local recurrence, three new and discrete growths had appeared. On the left tonsil there was an epitheliomatous ulcer, half an inch in diameter, which spread on to the soft palate but did not involve the tongue or the anterior pillar of the fauces. The sockets of the extracted molars were filled with fungating masses of epithelioma which though contiguous were quite distinct from one another. All of these growths were excised with diathermy cautery When the man died three months later, there was no sign of any recurrence in the mouth.

OTHER REPORTED CASES.

Spencer and Cade[1] report five similar examples:

(1) Male, aged 71. Four separate growths on the palate.

(2) Male, aged 53. A patient of Butlin who had four discrete epitheliomas on the border and under surface of the tongue and floor of the mouth as well as a rodent ulcer at the inner canthus of the eye.

(3) Female, aged 74. A papillary epithelioma on the left margin of the tongue, followed three months later by an epitheliomatous ulcer on the right lateral margin.

(4) Male, aged 57. Epithelioma involving the right lateral margin of the tongue and adjoining portion of the floor of the mouth and alveolus, followed three months later by an epithelioma developing on the soft palate.

(5) Male, aged 62. A papillary carcinoma on the left lateral margin of the tongue and an epitheliomatous ulcer on the right palato-glossal fold.

Fraser[2] in an investigation of 105 cases of buccal carcinoma found five cases of multiple primary growths. In one of these, however, the first growth to appear was a rodent ulcer of the left nostril. The other four cases were as follows: (1) Epithelioma of lower lip followed 14 years later by an epithelioma on the right palato-glossal fold. (2) Epithelioma of lower lip followed 14 years later by an epithelioma on the left palato-glossal fold. (3) Epithelioma of lower lip followed seven months later by an epithelioma on buccal surface of right cheek. (4) Epithelioma of left lateral margin of tongue followed eight years later by an epithelioma on the right lateral margin.

L. T. Owen[3] in a review of 3000 cases of malignant tumours found only two examples of multiple intra buccal growths—namely, (1) epithelioma of floor o mouth apparently cured but followed seven year later by an epithelioma on the alveolus; (2) a epithelioma on the right margin of the tongue followe three years later by an epithelioma on the left borde

PRIMARY OR SECONDARY?

These examples seem to suggest that cases such a Lord Moynihan's, though uncommon, occur mor frequently than is generally supposed.

Are the lesions multiple primary tumours or a they produced by metastasis or implantation Billroth[4] emphasised the importance of the criteri used as a basis for diagnosis and established thes postulates which he *felt* were necessary for the diagnosis of multiple malignant neoplasms:—

(1) Each tumour must have an independent histolog appearance. (2) The tumours must arise in different situ tions. (3) Each tumour must produce its own metastasis.

Mercanton[5] suggested the addition of a fourt postulate—namely, no recurrence of the tumou after their removal.

It seems to be as unreasonable to demand the fu fillment of the third and fourth postulates in t diagnosis of multiple primary carcinomata as it wou be in the diagnosis of a single carcinoma, a insistence on Billroth's first postulate would put o of court all the cases that I have quoted.

We may consider that Billroth's criteria are unnece sarily stringent, but in view of the general and we founded clinical conception of cancer as a conditi arising from a single focus of *origin* but acquiri multiple secondary foci of development, the burd

'oof is, indeed, upon one who assumes a case to
rate multiplicity of primary malignant tumours,
there are so many possibilities of error in obser-
n and interpretation that one should approach
ubject with extreme reserve, and that only after
ully considering the possibility of metastasis or
antation.

is highly improbable that cases of multiple intra-
al carcinomata can be explained away as examples
etastasis, for, though epithelioma of the tongue
s an almost constant invasion of the lymphatic
ds, secondary deposits elsewhere are extremely
Moreover, if these multiple tumours were the
lt of metastasis, we should expect to find secondary
ths in other parts of the body as well.

ver 250 years ago, with only the knowledge and
ow views of his day, Tulpius, the Dutch anatomist,
of the principal figures in Rembrandt's master-
e, "The Anatomist," said: "Cancer is just as con-
us as inflammation of the eyes." Doubtless this
a exaggerated statement, but there has accumu-
l much clinical and experimental proof that cancer
ccasionally communicated from host to host or
n one part of the body to another. Among the
t striking examples are those showing the spread
ancer of one side of the vulva to the other.
Bergmann[6] recorded a case of a man with a
er of the lower lip and exactly opposite to it on
upper lip was a similar growth, and Macewen[7]
s of a man with an epitheliomatous ulcer of his lip
had contracted the habit of rubbing the ulcer
then the tip of his nose with the same finger.
nty months after the removal of the growth on
lip, he returned with a large ulcer on the tip of the nose identical microscopically with the original tumour. Shimmelbusch[8] reported a similar case of apparent cancerous infection of the lip through the finger-nails of a person with an epithelioma of his ear.

There appears to be no doubt that implantation carcinoma of the mucosa of the alimentary canal has occurred on many occasions and that traumatised tissues are an especially fertile bed for this development. Hoche[9] has reported an epithelioma arising in the centre of a gastric ulcer in a patient with carcinoma of the œsophagus, and Dowden,[10] Challier,[11] among others, have described cases of implantation arising in colostomies from carcinoma of the large bowel. The development of carcinoma in the tooth-sockets in the case I have reported would seem without doubt to be another example of auto-inoculation or implantation and it would be illogical to invoke a different explanation of the origin of the carcinoma on the left tonsil in the same case. Probably many of the other cases of so-called multiple primary carcinomata of the buccal cavity are in reality examples of cancerous implantation.

CASE OF ENTERO-MESENTERIC CYST

SIMULATING ACUTE RETENTION OF URINE.

By H. J. Shorvon, M.R.C.S. Eng.,
E HOUSE PHYSICIAN, ST. OLAVE'S HOSPITAL, ROTHERHITHE;
AND
L. Wells, M.R.C.S. Eng.,
RESIDENT MEDICAL OFFICER, ST. OLAVE'S HOSPITAL.

NTERO-MESENTERIC cysts often give the symptoms
l signs of various acute abdominal conditions such
acute appendicitis, intussusception, volvulus, or
estinal obstruction, but we cannot find any record
it simulating a case of acute retention of urine.
e failure to pass urine, together with the presence
a swelling in the abdomen having the shape and
nsistency of a large palpable bladder but which at
eration was found to be an intraperitoneal cyst,
nder this case an unusually interesting one.

REPORT OF CASE.

Past history.—The mother stated that the boy had always
en a delicate child and had often complained of tenderness
the lower part of the abdomen, with vague abdominal
mptoms. He had an attack of "catarrhal jaundice"
en aged 6, and 18 months ago was in bed for several
nths with acute rheumatism. He was also admitted to
spital in February, 1929, with a provisional diagnosis of
estinal obstruction. The hospital notes of that time state
at he had a history of continual vomiting of green fluid
a week with constipation. He appeared very ill, had a
nken look on admission, with sordes on his lips. On
amination of the abdomen no peristalsis was observed,
was doughy to palpation, no tumour was felt, but free
id was present. Paracentesis abdominis was performed and a straw-coloured fluid withdrawn. The pathological report stated that no tubercle bacilli were detected, cells were present, mainly small lymphocytes and endothelial cells. The culture was sterile. The constipation was treated, condition subsided, and patient was sent to a convalescent home some weeks later with a final diagnosis of tuberculous peritonitis. An interesting point bearing on his subsequent history was the fact that during his stay in hospital the patient had considerable difficulty in passing urine, and his foreskin was slit in an attempt to remedy this.

History of present attack.—The patient, now aged 8, was admitted to hospital on June 6th, 1931, with the diagnosis of acute retention of urine. A day before admission the boy returned from school in a collapsed state, was giddy, faint, and complained of pains in his abdomen. He was given an aperient and bowels were freely opened. He did not micturate that day, was very parched, drank freely, and was very restless during the night owing to the abdominal pain. He vomited that night and twice in the morning. On admission to hospital the patient was pale, thin, dull, and toxic, with a coated dry tongue. Temperature, 100·4° F.; pulse-rate, 100; respiration, 22. The abdomen was rigid, and a hard tender swelling was palpated in the mid-line reaching to half an inch below the umbilicus. There was free fluid in the flanks. The respiratory and central nervous systems were normal. A rubber catheter was passed without difficulty but no more than 4 ounces of urine was collected. Later another catheter was passed, but this time no urine came through. A catheter was passed under general anæsthesia in the theatre, but again no urine was withdrawn.

Operation.—A right paramedian incision was made. On opening the peritoneum free yellow fluid was found, and a large, fairly thin-walled intraperitoneal cyst was exposed. The cyst was the size and shape of a large coco-nut, was smooth, and had a pale greenish appearance. It was continuous with, and attached to the mesentery of the small intestine, near its fixation to the posterior abdominal wall, and was fairly mobile on its attachment. The attachment was broad with myxomatous appearance, and the small gut in one portion (about 1½ inches) was attached to it. The cyst was aspirated and some yellow fluid evacuated. It was then incised, and yellow jelly-like material was expressed. The inner lining of the cyst was very red and œdematous.

represent the patient's point of view.

It is, of course, a fallacy that the post-cards were all sent out at the same time—that is, at greatly varying intervals after discharge, but as this was the same in both series the comparison still holds good. It was noted that there was no evidence of greater benefit in 92 patients who received autogenous vaccines than in the vaccine-treated group as a whole.

The conclusion is therefore that, within the limits of the inquiry, vaccines do not appear to hold out any better prospect of improvement or cure of infective arthritis than the other methods of treatment in use.

MULTIPLE MALIGNANT GROWTHS OF THE BUCCAL CAVITY.

By J. Bagot Oldham, M.B. Liverp., F.R.C.S. Eng.,
ASSISTANT HON. SURGEON TO THE NORTHERN HOSPITAL, LIVERPOOL; HON. SURGEON TO THE GENERAL HOSPITAL, BIRKENHEAD.

Lord Moynihan's clinical note on a Case of Primary Carcinoma developing, at intervals, in three different parts of the buccal cavity (The Lancet, Jan. 2nd) and his statement that he has "never before seen two primary malignant growths in the mouth" prompts me to report the following case.

On March 16th, 1931, a man. aged 62, was admitted into the David Lewis Northern Hospital, Liverpool. He complained that for three months he had been troubled by "soreness of his gums" on the left side. His mouth was edentulous and on the left side there was an epitheliomatous ulcer involving the floor of the mouth and the alveolus. The epithelioma was some two and a half inches long and extended back on to the fauces. The tongue could only be protruded half an inch beyond the gums and deviated to the left. The Wassermann reaction was negative. No involvement of the glands could be detected.

The growth was treated with surface application of radium on a plaque and when he was seen a month later the mouth seemed to be normal, the ulcer had healed up, and the induration of the floor of the mouth had gone. In July, however, he returned, complaining of severe pain in his left ear. On examination marked induration and thickening was found posteriorly in the angle between the tongue, the mandible, and the fauces. Radium was again applied. He returned for examination at intervals and appeared to be progressing well. The induration and the earache disappeared.

On Nov. 26th he came up for routine re-examination. He said he had come for his discharge as he had no pain and was sure he was cured. When I asked to see his mouth he protruded his tongue fully one and a half inches and deviated it well over to the right side so that I could examine the left side of his mouth. There was no sign of any recurrence of malignant disease on the left side. No glandular enlargement could be felt on the left side but, to my surprise, I found a hard mass of glands in the right submaxillary region and on the floor of the mouth, on the right side anteriorly, just under the tongue was the cause of this—a small indurated and ulcerated plaque, one centimetre in diameter. This plaque presented all the characteristics of an epithelioma. The patient was quite unconscious and even incredulous of this new development and at first refused to undergo further treatment. Later he consented to come into hospital and radium needles were inserted into the epithelioma and into the cervical glands.

In The Lancet of Oct. 26th, 1929, p. 873, I reported a case of Implantation of Epithelioma in the Alveoli of the Maxilla from primary growth in tongue which show similar features to Lord Moynihan's case. The main features of this case were as follows :—

A man aged 50 years. A very large epitheliomatous ulcer on right side of the tongue extending back on to right palato-glossal fold was excised with diathermy two weeks after the first and second right upper molars had been extracted. Ten weeks later he returned for re-examination and it was found though the tongue had completely healed an no sign of a local recurrence, three new and discr had appeared. On the left tonsil there was a matous ulcer, half an inch in diameter, which sp the soft palate but did not involve the tongue or t pillar of the fauces. The sockets of the extract were filled with fungating masses of epitheli though contiguous were quite distinct from on All of these growths were excised with diatherm When the man died three months later, there w of any recurrence in the mouth.

OTHER REPORTED CASES.

Spencer and Cade[1] report five similar exan

(1) Male, aged 71. Four separate growths on th

(2) Male, aged 53. A patient of Butlin who discrete epitheliomas on the border and under surf tongue and floor of the mouth as well as a roden the inner canthus of the eye.

(3) Female, aged 74. A papillary epithelioma o margin of the tongue, followed three months lat epitheliomatous ulcer on the right lateral margin.

(4) Male, aged 57. Epithelioma involving the rig margin of the tongue and adjoining portion of th the mouth and alveolus, followed three months lat epithelioma developing on the soft palate.

(5) Male, aged 62. A papillary carcinoma on lateral margin of the tongue and an epitheliomat on the right palato-glossal fold.

Fraser[2] in an investigation of 105 cases of carcinoma found five cases of multiple growths. In one of these, however, the first to appear was a rodent ulcer of the left nostril other four cases were as follows: (1) Epith of lower lip followed 14 years later by an epith on the right palato-glossal fold. (2) Epitheli lower lip followed 14 years later by an epithelio the left palato-glossal fold. (3) Epithelioma of lip followed seven months later by an epithelio buccal surface of right cheek. (4) Epithelioma lateral margin of tongue followed eight years by an epithelioma on the right lateral margin.

L. T. Owen[3] in a review of 3000 cases of mali tumours found only two examples of multiple buccal growths—namely, (1) epithelioma of flo mouth apparently cured but followed seven later by an epithelioma on the alveolus; (2 epithelioma on the right margin of the tongue foll three years later by an epithelioma on the left bo

PRIMARY OR SECONDARY ?

These examples seem to suggest that cases suc Lord Moynihan's, though uncommon, occur frequently than is generally supposed.

Are the lesions multiple primary tumours or they produced by metastasis or implantati Billroth[4] emphasised the importance of the crit used as a basis for diagnosis and established th postulates which he felt were necessary for the di nosis of multiple malignant neoplasms :—

(1) Each tumour must have an independent histol appearance. (2) The tumours must arise in different sit tions. (3) Each tumour must produce its own metastasi

Mercanton[5] suggested the addition of a fou postulate—namely, no recurrence of the tumo after their removal.

It seems to be as unreasonable to demand the fu fillment of the third and fourth postulates in t diagnosis of multiple primary carcinomata as it wou be in the diagnosis of a single carcinoma, an insistence on Billroth's first postulate would put ou of court all the cases that I have quoted.

We may consider that Billroth's criteria are unnece sarily stringent, but in view of the general and wel founded clinical conception of cancer as a conditio arising from a single focus of origin but acquirin multiple secondary foci of development, the burde

the principal figures in Rembrandt's master-
"The Anatomist," said: "Cancer is just as con-
as inflammation of the eyes." Doubtless this
xaggerated statement. but there has accumu-
uch clinical and experimental proof that cancer
sionally communicated from host to host or
ne part of the body to another. Among the
triking examples are those showing the spread
cer of one side of the vulva to the other.
ergmann[6] recorded a case of a man with a
of the lower lip and exactly opposite to it on
per lip was a similar growth. and Macewen[7]
a man with an epitheliomatous ulcer of his lip
ad contracted the habit of rubbing the ulcer
en the tip of his nose with the same finger.
y months after the removal of the growth on
, he returned with a large ulcer on the tip of the nose identical microscopically with the original tumour. Shimmelbusch[8] reported a similar case of apparent cancerous infection of the lip through the finger-nails of a person with an epithelioma of his ear.

There appears to be no doubt that implantation carcinoma of the mucosa of the alimentary canal has occurred on many occasions and that traumatised tissues are an especially fertile bed for this development. Hoche[9] has reported an epithelioma arising in the centre of a gastric ulcer in a patient with carcinoma of the œsophagus. and Dowden.[10] Challier,[11] among others, have described cases of implantation arising in colostomies from carcinoma of the large bowel. The development of carcinoma in the tooth-sockets in the case I have reported would seem without doubt to be another example of auto-inoculation or implantation and it would be illogical to invoke a different explanation of the origin of the carcinoma on the left tonsil in the same case. Probably many of the other cases of so-called multiple primary carcinomata of the buccal cavity are in reality examples of cancerous implantation.

CLINICAL AND LABORATORY NOTES

ASE OF ENTERO-MESENTERIC CYST

MULATING ACUTE RETENTION OF URINE.

By H. J. Shorvon, M.R.C.S. Eng.,
OUSE PHYSICIAN, ST. OLAVE'S HOSPITAL, ROTHERHITHE;
AND
L. Wells, M.R.C.S. Eng.,
ESIDENT MEDICAL OFFICER, ST. OLAVE'S HOSPITAL.

ERO-MESENTERIC cysts often give the symptoms
igns of various acute abdominal conditions such
ute appendicitis. intussusception. volvulus. or
inal obstruction. but we cannot find any record
simulating a case of acute retention of urine.
ailure to pass urine. together with the presence
swelling in the abdomen having the shape and
stency of a large palpable bladder but which at
tion was found to be an intraperitoneal cyst.
r this case an unusually interesting one.

REPORT OF CASE.

history.—The mother stated that the boy had always
a delicate child and had often complained of tenderness
lower part of the abdomen. with vague abdominal
oms. He had an attack of "catarrhal jaundice"
aged 6. and 18 months ago was in bed for several
s with acute rheumatism. He was also admitted to
al in February. 1929, with a provisional diagnosis of
nal obstruction. The hospital notes of that time state
he had a history of continual vomiting of green fluid
week with constipation. He appeared very ill. had a
n look on admission. with sordes on his lips. On
ination of the abdomen no peristalsis was observed.
s doughy to palpation. no tumour was felt. but free
was present. Paracentesis abdominis was performed and a straw-coloured fluid withdrawn. The pathological report stated that no tubercle bacilli were detected. cells were present. mainly small lymphocytes and endothelial cells. The culture was sterile. The constipation was treated. condition subsided, and patient was sent to a convalescent home some weeks later with a final diagnosis of tuberculous peritonitis. An interesting point bearing on his subsequent history was the fact that during his stay in hospital the patient had considerable difficulty in passing urine. and his foreskin was slit in an attempt to remedy this.

History of present attack.—The patient. now aged 8. was admitted to hospital on June 6th. 1931, with the diagnosis of acute retention of urine. A day before admission the boy returned from school in a collapsed state. was giddy. faint. and complained of pains in his abdomen. He was given an aperient and bowels were freely opened. He did not micturate that day. was very parched. drank freely. and was very restless during the night owing to the abdominal pain. He vomited that night and twice in the morning. On admission to hospital the patient was pale. thin. dull. and toxic. with a coated dry tongue. Temperature. 100·4° F.; pulse-rate. 100; respiration. 22. The abdomen was rigid, and a hard tender swelling was palpated in the mid-line reaching to half an inch below the umbilicus. There was free fluid in the flanks. The respiratory and central nervous systems were normal. A rubber catheter was passed without difficulty but no more than 4 ounces of urine was collected. Later another catheter was passed. but this time no urine came through. A catheter was passed under general anæsthesia in the theatre. but again no urine was withdrawn.

Operation.—A right paramedian incision was made. On opening the peritoneum free yellow fluid was found. and a large. fairly thin-walled intraperitoneal cyst was exposed. The cyst was the size and shape of a large coco-nut. was smooth. and had a pale greenish appearance. It was continuous with. and attached to the mesentery of the small intestine. near its fixation to the posterior abdominal wall. and was fairly mobile on its attachment. The attachment was broad with myxomatous appearance. and the small gut in one portion (about 1¼ inches) was attached to it. The cyst was aspirated and some yellow fluid evacuated. It was then incised. and yellow jelly-like material was expressed. The inner lining of the cyst was very red and œdematous.

as both the statement as to condition on admission and the reply to the post-card represent the patient's point of view.

It is, of course, a fallacy that the post-cards were all sent out at the same time—that is, at greatly varying intervals after discharge, but as this was the same in both series the comparison still holds good. It was noted that there was no evidence of greater benefit in 92 patients who received autogenous vaccines than in the vaccine-treated group as a whole.

The conclusion is therefore that, within the limits of the inquiry, vaccines do not appear to hold out any better prospect of improvement or cure of infective arthritis than the other methods of treatment in use.

MULTIPLE MALIGNANT GROWTHS OF THE BUCCAL CAVITY.

By J. Bagot Oldham, M.B. Liverp., F.R.C.S. Eng.,
ASSISTANT HON. SURGEON TO THE NORTHERN HOSPITAL, LIVERPOOL; HON. SURGEON TO THE GENERAL HOSPITAL, BIRKENHEAD.

Lord Moynihan's clinical note on a Case of Primary Carcinoma developing, at intervals, in three different parts of the buccal cavity (The Lancet, Jan. 2nd) and his statement that he has "never before seen two primary malignant growths in the mouth" prompts me to report the following case.

On March 16th, 1931, a man, aged 62, was admitted into the David Lewis Northern Hospital, Liverpool. He complained that for three months he had been troubled by "soreness of his gums" on the left side. His mouth was edentulous and on the left side there was an epitheliomatous ulcer involving the floor of the mouth and the alveolus. The epithelioma was some two and a half inches long and extended back on to the fauces. The tongue could only be protruded half an inch beyond the gums and deviated to the left. The Wassermann reaction was negative. No involvement of the glands could be detected.

The growth was treated with surface application of radium on a plaque and when he was seen a month later the mouth seemed to be normal, the ulcer had healed up, and the induration of the floor of the mouth had gone. In July, however, he returned, complaining of severe pain in his left ear. On examination marked induration and thickening was found posteriorly in the angle between the tongue, the mandible, and the fauces. Radium was again applied. He returned for examination at intervals and appeared to be progressing well. The induration and the earache disappeared.

On Nov. 26th he came up for routine re-examination. He said he had come for his discharge as he had no pain and was sure he was cured. When I asked to see his mouth he protruded his tongue fully one and a half inches and deviated it well over to the right side so that I could examine the left side of his mouth. There was no sign of any recurrence of malignant disease on the left side. No glandular enlargement could be felt on the left side but, to my surprise, I found a hard mass of glands in the right submaxillary region and on the floor of the mouth, on the right side anteriorly, just under the tongue was the cause of this—a small indurated and ulcerated plaque, one centimetre in diameter. This plaque presented all the characteristics of an epithelioma. The patient was quite unconscious and even incredulous of this new development and at first refused to undergo further treatment. Later he consented to come into hospital and radium needles were inserted into the epithelioma and into the cervical glands.

In The Lancet of Oct. 26th, 1929, p. 873, I reported a case of Implantation of Epithelioma in the Alveoli of the Maxilla from primary growth in tongue which show similar features to Lord Moynihan's case. The main features of this case were as follows:—

A man aged 50 years. A very large epitheliomatous ulcer on right side of the tongue extending back on to right palato-glossal fold was excised with diathermy two weeks after the first and second right upper molars had been extracted. Ten weeks later he returned for re-examination and it was found that, though the tongue had completely healed and there was no sign of a local recurrence, three new and discrete growths had appeared. On the left tonsil there was an epitheliomatous ulcer, half an inch in diameter, which spread onto the soft palate but did not involve the tongue or the anterior pillar of the fauces. The sockets of the extracted molars were filled with fungating masses of epithelioma which though contiguous were quite distinct from one another. All of these growths were excised with diathermy cautery. When the man died three months later, there was no sign of any recurrence in the mouth.

OTHER REPORTED CASES.

Spencer and Cade[1] report five similar examples:

(1) Male, aged 71. Four separate growths on the palate.

(2) Male, aged 53. A patient of Butlin who had four discrete epitheliomas on the border and under surface of the tongue and floor of the mouth as well as a rodent ulcer at the inner canthus of the eye.

(3) Female, aged 74. A papillary epithelioma on the left margin of the tongue, followed three months later by an epitheliomatous ulcer on the right lateral margin.

(4) Male, aged 57. Epithelioma involving the right lateral margin of the tongue and adjoining portion of the floor of the mouth and alveolus, followed three months later by an epithelioma developing on the soft palate.

(5) Male, aged 62. A papillary carcinoma on the left lateral margin of the tongue and an epitheliomatous ulcer on the right palato-glossal fold.

Fraser[2] in an investigation of 105 cases of buccal carcinoma found five cases of multiple primary growths. In one of these, however, the first growth to appear was a rodent ulcer of the left nostril. Th other four cases were as follows: (1) Epitheliom of lower lip followed 14 years later by an epitheliom on the right palato-glossal fold. (2) Epithelioma lower lip followed 14 years later by an epithelioma the left palato-glossal fold. (3) Epithelioma of low lip followed seven months later by an epithelioma buccal surface of right cheek. (4) Epithelioma of le lateral margin of tongue followed eight years lat by an epithelioma on the right lateral margin.

L. T. Owen[3] in a review of 3000 cases of maligna tumours found only two examples of multiple int buccal growths—namely, (1) epithelioma of floor mouth apparently cured but followed seven ye later by an epithelioma on the alveolus; (2) epithelioma on the right margin of the tongue follov three years later by an epithelioma on the left bord

PRIMARY OR SECONDARY?

These examples seem to suggest that cases such Lord Moynihan's, though uncommon, occur m frequently than is generally supposed.

Are the lesions multiple primary tumours or they produced by metastasis or implantati Billroth[4] emphasised the importance of the crit used as a basis for diagnosis and established t postulates which he felt were necessary for the d nosis of multiple malignant neoplasms:—

(1) Each tumour must have an independent histo appearance. (2) The tumours must arise in different s tions. (3) Each tumour must produce its own metastas

Mercanton[5] suggested the addition of a fo postulate—namely, no recurrence of the tum after their removal.

It seems to be as unreasonable to demand the fillment of the third and fourth postulates in diagnosis of multiple primary carcinomata as it wo be in the diagnosis of a single carcinoma, insistence on Billroth's first postulate would put of court all the cases that I have quoted.

We may consider that Billroth's criteria are unne sarily stringent, but in view of the general and w founded clinical conception of cancer as a condi arising from a single focus of origin but acqui multiple secondary foci of development, the bur walnut. The right kidney is normal, while the shows a moderate degree of hydronephrosis, due to the large lymph glands pressing on the enlarged lymph glands found elsewhere.

ıse the patient's symptoms on admission ly pulmonary and remained so until re the end. Moreover, the nature of the symptoms—viz., those of a pyopneumo- ɔne not often associated with Hodgkin's were there any symptoms or signs of the detected in any other part of the body, ɔf the results of accessory examinations. s no doubt that in this case the trouble he deep-seated lymph glands, whether ıbdominal or both it is not possible to be ıistory only dates from about three months ssion.

back from the vantage point of the seems probable that the pain in the back pressure on the left ureter from the lominal glands, whilst the list of repeated everishness fits in with the existence of ma. Actually, however, after admission, up to the time of the onset of acute few days before death, there was nothing be felt in the abdomen, nor were there any eferable to it. The spleen was never s the pneumothorax increased the liver down and its edge felt below the costal it seemed normal.

orax is not a common accompaniment of lymphadenoma. R. I. Köttler[1] in 1930, when recording such a case, states that, "from available literature" it would appear that "his case is unique." So far as we have had the opportunity of making a review, we have found no other reference to its occurrence. On the other hand, it is not uncommon for lymphadenomatous changes to be found in the lungs; and although E. Kaufmann[2] states that such changes are often seen along the bronchi and arteries, we regard the pneumothorax as an accident following a more or less fortuitous chain of circumstances. In our case the lymphadenomatous infiltration of the mucosa of certain small bronchi probably caused some obstruction of the lumina, as was indicated by the diminished movements and expansion seen clinically; hence, retained secretion and secondary infection producing the abscess. This doubtless ruptured at some time into the pleura, although at autopsy no actual communication was found. The microscopic sections show that the abscess in the lung was not due to the breaking down of lymphadenomatous tissue.

Köttler's case was that of a woman, aged 23, and the duration of illness was eight months. There was weakness, fever, and wasting, and later enlarged glands in neck and axilla. She had cough, dyspnœa, and right pleurisy. The spleen was just palpable later. Ten days before death serous fluid was drawn off from right pleura and an unsuspected pneumothorax found. At autopsy a large tracheal gland was found to have broken down and formed a fistula into the œsophagus. In the upper part of the right lung were confluent foci of breaking-down material, which in one place had joined together and left a cavity the size of a walnut, with a hole (1 by 2 cm.) into the pleura. He regards this as a secondary infection of the lung in a case of Hodgkin's disease.

---

[1] Zeit. f. Tuberk., 1930, lviii., 37.

[2] Lehrbuch d. Spezieller Pathologischen Anatomie, 1922, Berlin, p. 205.

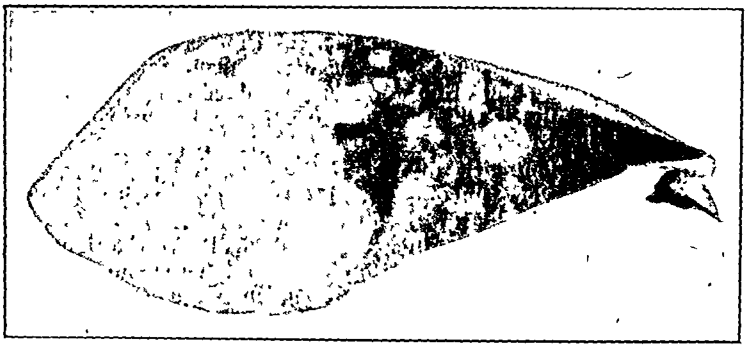
STAFFORDSHIRE POOR-LAW INSTITUTIONS.—The Staffordshire public assistance committee has prepared plans and estimates for the reorganisation of hospital accommodation which involve the expenditure of £243,000. It is proposed to convert the Newcastle institution into a hospital of 400 beds for the northern part of the county, and to do the same with the Wordsley institution for the southern portion. The estimated cost of the Newcastle scheme is £175,000, and of the Wordsley scheme £68,000.

WAKEFIELD FEVER HOSPITAL.—The city council are not proceeding with a suggested scheme for the erection of a new hospital at a cost of £71,000, but will improve and extend the existing one, upon which the medical officer, Dr. T. Gibson, has made a strongly unfavourable report. He condemns the present site on several grounds. It is on the smoke-laden side of the town, is increasingly surrounded by houses, the main ward pavilions are within a few feet of a public road, involving noise amounting at times to a nuisance. The windows are broken by stone-throwing from without, and there is sometimes undesirable communication between patients and outsiders. Dr. Gibson finds that the hospital does not lend itself satisfactorily to extension, and that it is not suitable for the treatment of cases of tuberculosis. There are 24 beds instead of the 60 at least that are necessary for ordinary infectious diseases. The ventilation is "quite inadequate," the hot water supply "very poor," and the gas lighting "miserable." This insufficient lighting is sometimes "a positive danger," as when a tracheotomy operation has to be performed in the middle of the night. At times more than one disease has had to be treated in one ward; there are no side wards for septic cases or dying patients, and "operations have to be performed in the wards, surrounded by screens." Dr. Gibson adds that "were it not for an adaptable and competent nursing staff public confidence in the hospital would have been shattered long ago."

all this time. She was then up and about again but still feeling very ill.

Two weeks before admission the weakness became worse and she developed a cough and sore-throat. She also complained of a stabbing pain in the right side, which was made worse by coughing or taking a deep breath; it was so severe that it made her "scream out." Her breathing has also been "heavy." This stabbing pain lasted for about a week.

FIG. 1.



Photograph to show the tumour-like mass in the liver.

On May 18th a needle had been put into the right chest but no fluid was obtained.

The personal and family history gave no information of importance. Her general functions are normal except that the menses ceased in January, 1931, for the first time. They had always been regular before.

Examination (May 25th).—A small spare woman propped up in bed. Respiration-rate 40, with obvious distress; temperature, 102° F.; pulse-rate, 152. Full examination showed no abnormal signs in the nervous system, no superficial glandular enlargement, no changes in the limbs. Nothing abnormal to be seen or felt in the abdomen; the spleen was not palpable. The abnormal conditions were apparently quite limited to the thorax. The heart was in its normal position; no murmurs were present. Chest expansion was much diminished. The chest was poorly developed. Rhonchi were heard here and there over both lungs. Movement was diminished on the right side, and at the right base there was complete dullness with absence of breath sounds. No tubercle bacilli were found in the sputa.

Course of Illness.—During the next few days she remained much the same, the temperature ranging each day from normal to 102° F. The respirations came down to 28, and the pulse-rate varied from 120 to 130. There was a trace of albumin in the urine. She complained of more pain in the right chest, cough, and shortness of breath.

Radiography on May 30th showed restricted movement of the right diaphragm. The heart small; normal in position. Partial collapse of the right lung, and an area of pneumothorax occupying the costophrenic angle. Marked fibrosis extending from the right hilum towards the base. This was evidently the beginning of the pneumothorax, for when the patient was last examined there had been no signs of it.

During the next few days her condition became worse—the temperature began to swing more, the pneumothorax increased rapidly, and signs of some fluid appeared at the right base. The mediastinum and heart were displaced to the left. On June 5th a second radiogram confirmed these findings. On June 6th the chest was punctured by the medical registrar, Dr. T. E. Gumpert. It was found that there was a negative pressure −2 to −6: 270 c.cm. of air was injected to restore a pressure of zero (−3 : +3).

A blood count on June 3rd showed: red cells, 3,700,000; hæmoglobin, 35 per cent.; white cells, 11,400; platelets, 250,000. Of the leucocytes 95 per cent. were polymorphs, with many young forms. No eosinophils seen.

On June 11th, 270 c.cm. of streptococcal pus were removed. Again the pressure before doing this was −2 : −8 : and was afterwards brought to zero (−2 +2) by replacement of 250 c.cm. of air. After this her condition improved somewhat. Blood cultures were negative. Repeated examinations showed no change in the physical signs. There was a large pneumothorax on the right side with a small quantity of movable dullness at the base. The temperature remained about the same as before. The liver edge was about two inches below the costal margin; it was smooth and apparently normal. The spleen was not palpable. There were no abnormal physical signs in parts. No petechiæ. No cardiac murmurs.

On July 6th she vomited after taking her morn of medicine and complained during the day of l appetite. Later in the day she began suddenly with pain in the abdomen. On examination the abdom distended, rigid, and very tender—more on the righ than the left. It was evic

and after

Simpson,

pulmonary condition present, o interference did not offer any lik of benefit. She died on July 9th autopsy was performed on the fol day.

AUTOPSY.

Externally.—Slight œdema of l extremities.

Thorax.—Pyopneumothorax in pleural cavity, with several pints from which hæmolytic strepto obtained in pure culture. Dense adhesions in left pleural cavity. displaced to left side, but otherwise Much frothy secretion in the air The mucosa of the lower end of the has a slightly granular surface. The main bronchus shows thickening mucous membrane with a flat protuberance not obviously ulcerat 5 mm. in diameter, situated a q an inch from the bifurcation of the Around the bronchus and extendi its branches into the lung is considerable fi right lung is collapsed, with thickened pleura a genic membrane on the surface. In the lower part upper lobe, just under the surface, is an abscess of a cherry, but with no obvious leakage of pus pleura. At the base of the lower lobe is a firm solid about as large as a pea. The left lung is very œdema and there is bronchitis. The glands at the root of the l are enlarged, reaching a maximum of about one in diameter. The smaller ones are discrete, but the larg heavily pigmented and surrounded by fibrous tissue, adh to the right bronchus.

Abdomen.—General purulent peritonitis, hæm streptococci isolated in pure culture. The sto intestines, pancreas, and suprarenals are normal. liver weighs 48 oz. The anterior margin appears n

down

They are fleshy and discrete, the largest reaching n the substances when mention was made of producing hormone. The ketone gave its um response 24 hours after injection, whereas itrodroxyl compound gave a longer latent and a much more prolonged response. Dr. n suggested that further work should be ted by using injections of the crystalline al only in order to obtain clear-cut results.

ACTIONS OF ENDOMETRIUM AND UTERINE MUSCLE.

J. M. ROBSON said that it was important to something of the sex cycle in the human in to understand the action of these hormones. the influence of the corpus luteum hormone the etrium was built up during the latter half of nstrual cycle, to degenerate with the occurrence nstruation. There was also a change in the e muscle when under the influence of the a lutea, in that it would not respond to in. Similarly the uterine muscle of a virgin l which had been injected with corpus luteum t did not respond to pituitrin; nor did the nt uterus, but at term the corpus luteum ed. An observer who had inserted bags cted to manometers into the human uterus hown that intravenous injection of pituitrin l contraction during the first half only of the It was likely that the reactions in the netrium and the muscle were independent and be dissociated; dysmenorrhœa would result the pituitary acted on a uterus whose endoum had not fully degenerated. Cases of enorrhœa, secondary amenorrhœa, and habitual ion had all shown improvement after treatment œstrin; those of primary amenorrhœa had not.

. T. C. CLARE disputed the current interpretation e fact that an ovary-stimulating substance was l during pregnancy in urine. This hormone, gued, must be a chemical substance and as such be fixed or absorbed by activity. When, fore, it was being excreted unchanged it was r being produced in excess of the body's need, se the demand had been reduced. This fixation t be physiological or pathological. It would be esting to know if the Aschheim-Zondek reaction positive in a young woman immediately after erectomy. An appreciable proportion of cases alignant disease of the uterus had given a positive tion; this fact might be significant in the logy of cancer. He suggested that it was merely to excess of hormone as the uterus was failing to he full quantity.

r. MARRIAN, in reply, said that Mr. Clare's theory based on a false supposition that the presence he hormone in urine indicated failure of fixation. hing was known of the nature of the hormone; as was possible, it acted like a catalyst, argu- ts based on quantitative fixation would fall he ground.

he PRESIDENT said that there was no doubt that y claims in the past for the extracts had been ard. The cause of the profusion was the confusion of post and propter hoc; it was so easy to forget the on of chance. A girl of 20 was given an extract afterwards started to menstruate; although the nces might be ten to one that she would do so in case, it was tempting to attribute falsely the nstruation to the treatment. He hoped that en obstetricians or gynæcologists had clear-cut es they would refer them to a biochemist who ld make good scientific use of the case. Surely it should be easy to refer to the biochemist the problem of how much use was the ovary after hysterectomy.

Prof. DODDS said that hysterectomy led to a cystic condition of the ovaries which was abated by giving an extract of uterus.

The PRESIDENT suggested that as there was luteinisation of the ovaries in vesicular mole it would be interesting to examine the hormone content of vesicular moles when suitably large ones were available.

Demonstration of Specimens.

Mr. T. G. STEVENS showed a rhabdomyosarcoma of the cervix removed from an unmarried woman, aged 23, who had had slight intermenstrual bleeding for 12 months and recently a stabbing pain in the abdomen. The tumour which was attached to the cervix by only a thin pedicle was thought to be a large mucous polypus and was removed in the out-patients' department. Sections, however, showed small striated muscle-fibres, and also smooth muscle-fibres in a fibrous tissue stroma, and there was an incomplete covering of squamous epithelium. A few glands but no cartilage were present. Mr. Stevens considered that in spite of the presence of striped muscle tissue, which was unusual, the tumour was highly malignant; he therefore performed panhysteroöphorectomy. No secondaries were seen in the abdomen, and the growth ceased abruptly where the pedicle joined the cervix. Deep X ray therapy was subsequently given. Judging by all reported cases the prognosis was poor.—Dr. F. J. MCCANN said that he had seen a few cases which had contained cartilage. There had been early recurrence in each case.—The PRESIDENT reported that he had seen several cases of sarcoma during the last few years, but none had contained striped muscle tissue. In two cases operation had not been followed by recurrence. He doubted whether it was advisable to remove both ovaries, especially in so young a patient, although X ray therapy was given. He had seen recurrence in an ovary.—Mr. STEVENS replied that he held very strongly that ovaries after the removal of the uterus are of no use at all. He had removed both in this case because he wished to remove entire the whole lymph tract.

Mr. LOUIS C. RIVETT showed a foreign body which had been removed from the lumen of the small intestine ten years after he had performed Cæsarean section. Convalescence had been delayed, the patient stated that she had not felt well since then, but she had only recently consulted her doctor. On examination a mass was found in the upper abdomen. At an exploratory operation the intestines were found to be matted together and considerable anastomosis had occurred. A foreign body found within the lumen of the matted intestines was removed through a hole which was sutured and drained. The patient made a good recovery and afterwards only complained of slight diarrhœa. The foreign body which Mr. Rivett had in his own keeping proved to be extensive fæcal concretions round a large gall-stone.

POST-GRADUATE WORK IN BERLIN.—International medical post-graduate courses are to be held in Berlin on the following subjects: internal medicine (Feb. 29th to March 5th); occupation and disease (March 7th to 14th); recent results of scientific research and their employment in obstetrics and gynæcology (March 14th to 19th); surgery (April 4th to 9th); and practical progress in X ray diagnosis and treatment (April 10th to 17th). Particulars of these and of the regular courses may be had from the information bureau of the Kaiserin Friedrich-Haus, Luisenplatz, 2, Berlin, N.W.6.

considerable difficulties. Coward and Burn had shown by using large numbers of animals that as the amount of œstrin injected was increased, an increasing number of rats or mice showed œstrus. It had therefore become necessary to carry out standardisation on large numbers of animals and all previous quantitative work had been rendered useless. The point where 50 animals showed œstrus and 50 did not had, by common consent among workers, become the standard for œstrin. Other variations in the effectiveness of a dose were produced by the purity of the material and by the mode of administration. Very pure œstrin was excreted so rapidly that it was gone before œstrus occurred; larger doses were required for oral administration than for injection, and far fewer units were required for oral administration of crude œstrin than of the pure material. Furthermore, the activity of a quantity depended on the number of doses into which it was divided. Very little was known of the nature of the prolans except that they were complicated substances containing nitrogen.

Turning to the clinical application of this research Prof. Dodds said that œstrin had been recommended for every gynæcological condition—amenorrhœa, menorrhagia, hæmophilia, and a host of other conditions. The prolans had been similarly recommended. The expense of progestin, due to the difficulty of obtaining corpora lutea, was an obstacle to its clinical use. Probably all work in the past had been carried out grossly inadequate doses. He suggested that should be confined to clear-cut cases about which ch is known and that large doses of œstrin should o given. It should be possible to make preparations which would be slowly absorbed; large doses of crystalline material appeared to be wasteful and useless. The Aschheim-Zondek test for pregnancy was the only definite clinical aid that had so far come from this work. In conclusion, he offered a warning with regard to the indiscriminate use of prolan. It was known that the ovary of an animal could be converted into a solid mass of lutein tissue by the administration of this material and it would be undesirable to run any risk of producing this effect in women.

UNITS OF DOSAGE.

Prof. A. S. **Parkes** said that standard units as a measure of œstrus-producing hormone did not exist, but it would be possible to standardise the œstrus-producing hormone within 10 per cent. by the method of Coward and Burn. The test depended on the cornification of the vagina of a mouse or rat; in these animals the amount required to produce the cornification varied with the method of administration, the time over which it was spread, and the number of doses into which the material was split. Disregarding for the moment these large variations, the laboratory unit was a rat unit or a mouse unit. By keeping strictly to the same method with these two animals Prof. Dodds and Mr. G. F. Marrian, D.Sc., had shown that the dose required for rats was ten times that for mice. Cornification was only one symptom of œstrus and the amount of hormone required to produce full œstrus, judged by distension of the uterus, was found to be very much greater. Marrian had found that the necessary dose was about 200 times greater in the mouse and it was likely that a similar factor held for the rat. In larger animals the figures were still more startling. To produce œstrus in the ovariectomised ferret or rabbit the figures mounted rapidly into thousands and 100,000 mouse units were required to produce full œstrus in a baboon weighing 10 kg. The dosage was thus found strictly on a weight for weight basis, and so co the curve upwards the clinical dose becam million mouse units for a woman. Various preparations were on the market, one of wh 30*s*. for 2000 units. If half a million un necessary for a woman and this figure were m by 12½, the factor for oral administration, the one effective dose would be £9000. The rea dosage for clinical use was a very urgent and a revision of our ideas of the clinical tion of the œstrus-producing hormone was required.

CLINICAL TESTS.

Dr. H. **Gardiner-Hill** said that he ha provided by Prof. Dodds with standardised e of œstrin for four years. This material ha tried out on cases of amenorrhœa and of clin phenomena. He had classified the cases into t (1) primary amenorrhœa (normal individual delayed development, wasting diseases, and gla defects), (2) primary menstrual irregularities, were minor degrees of the first group, a secondary amenorrhœa. None of group 1, third of group 2; and in group 3 over half the of secondary amenorrhœa due to simple cause as climate, shock, or pregnancy had been af Secondary amenorrhœa due to glandular defec been unaffected. Two cases were striking; patients complained of amenorrhœa and ste both menstruated after injection of 180 and mouse units respectively, became pregnant an normal children. Dr. Gardiner-Hill thought preparations of œstrin such as those provide Prof. Dodds were worth further clinical trial in fully selected straightforward cases of amenor of the type he had discussed. He realised difficulty of assessing clinical results in these c tions, but nevertheless thought that it was di to account for the changes in his cases except o supposition that they had in some way resulted treatment with œstrin. When the relative size o human being and the experimental animals taken into consideration the effective dose cer seemed to be small, but the œstrus-producing in animals mentioned by Parkes appeared t quantitative. Could not the clinical result explained on the "trigger" hypothesis of W. Sh a small dose stimulating a sub-functioning foll apparatus to produce active follicles and so initi the cycle which ultimately resulted in the men discharge?

CHEMICAL CONSTITUTION.

Dr. Marrian said that in 1927 Aschheim and Zo discovered the presence of œstrus-producing hor in urine. The next step was in 1928 when I showed that the œstrus-producing hormone had acidic properties of a phenol. This gave the which led to the isolation by three indepen workers of a crystalline material with an empi formula of $C_{18}H_{22}O_2$. It proved to be a hydr ketone. A little later Dr. Marrian himself isolated an œstrus-producing compound with formula $C_{18}H_{24}O_3$ with three hydroxyl gro Butenandt had then shown that both these substa were present in the urine of pregnant women, that one could be converted into the other distillation with potassium sulphate; they therefore obviously related chemically. The of these ($C_{18}H_{22}O_2$) was more potent physiologic than the second, and a distinction should be en the substances when mention was made of s-producing hormone. The ketone gave its num response 24 hours after injection, whereas ritrodroxyl compound gave a longer latent l and a much more prolonged response. Dr. an suggested that further work should be cted by using injections of the crystalline ial only in order to obtain clear-cut results.

EACTIONS OF ENDOMETRIUM AND UTERINE MUSCLE.

J. M. ROBSON said that it was important to something of the sex cycle in the human in to understand the action of these hormones. r the influence of the corpus luteum hormone the netrium was built up during the latter half of enstrual cycle, to degenerate with the occurrence enstruation. There was also a change in the ne muscle when under the influence of the ra lutea, in that it would not respond to trin. Similarly the uterine muscle of a virgin al which had been injected with corpus luteum ct did not respond to pituitrin; nor did the nant uterus, but at term the corpus luteum ided. An observer who had inserted bags ected to manometers into the human uterus shown that intravenous injection of pituitrin ed contraction during the first half only of the . It was likely that the reactions in the metrium and the muscle were independent and d be dissociated; dysmenorrhœa would result n the pituitary acted on a uterus whose endo-ium had not fully degenerated. Cases of nenorrhœa, secondary amenorrhœa, and habitual tion had all shown improvement after treatment œstrin; those of primary amenorrhœa had not.

r. T. C. CLARE disputed the current interpretation he fact that an ovary-stimulating substance was d during pregnancy in urine. This hormone, rgued, must be a chemical substance and as such t be fixed or absorbed by activity. When, efore, it was being excreted unchanged it was er being produced in excess of the body's need, lse the demand had been reduced. This fixation ht be physiological or pathological. It would be resting to know if the Aschheim-Zondek reaction e positive in a young woman immediately after terectomy. An appreciable proportion of cases nalignant disease of the uterus had given a positive tion; this fact might be significant in the logy of cancer. He suggested that it was merely to excess of hormone as the uterus was failing to he full quantity.

r. MARRIAN, in reply, said that Mr. Clare's theory based on a false supposition that the presence he hormone in urine indicated failure of fixation. hing was known of the nature of the hormone; is was possible, it acted like a catalyst, argu-ts based on quantitative fixation would fall he ground.

ne PRESIDENT said that there was no doubt that y claims in the past for the extracts had been rd. The cause of the profusion was the confusion of post and propter hoc; it was so easy to forget the on of chance. A girl of 20 was given an extract afterwards started to menstruate; although the ces might be ten to one that she would do so in case, it was tempting to attribute falsely the struation to the treatment. He hoped that n obstetricians or gynæcologists had clear-cut they would refer them to a biochemist who make good scientific use of the case. Surely it should be easy to refer to the biochemist the problem of how much use was the ovary after hysterectomy.

Prof. DODDS said that hysterectomy led to a cystic condition of the ovaries which was abated by giving an extract of uterus.

The PRESIDENT suggested that as there was luteinisation of the ovaries in vesicular mole it would be interesting to examine the hormone content of vesicular moles when suitably large ones were available.

Demonstration of Specimens.

Mr. T. G. STEVENS showed a rhabdomyosarcoma of the cervix removed from an unmarried woman, aged 23, who had had slight intermenstrual bleeding for 12 months and recently a stabbing pain in the abdomen. The tumour which was attached to the cervix by only a thin pedicle was thought to be a large mucous polypus and was removed in the out-patients' department. Sections, however, showed small striated muscle-fibres, and also smooth muscle-fibres in a fibrous tissue stroma, and there was an incomplete covering of squamous epithelium. A few glands but no cartilage were present. Mr. Stevens considered that in spite of the presence of striped muscle tissue, which was unusual, the tumour was highly malignant; he therefore performed panhysteroöphorectomy. No secondaries were seen in the abdomen, and the growth ceased abruptly where the pedicle joined the cervix. Deep X ray therapy was subsequently given. Judging by all reported cases the prognosis was poor.—Dr. F. J. MCCANN said that he had seen a few cases which had contained cartilage. There had been early recurrence in each case.—The PRESIDENT reported that he had seen several cases of sarcoma during the last few years, but none had contained striped muscle tissue. In two cases operation had not been followed by recurrence. He doubted whether it was advisable to remove both ovaries, especially in so young a patient, although X ray therapy was given. He had seen recurrence in an ovary.—Mr. STEVENS replied that he held very strongly that ovaries after the removal of the uterus are of no use at all. He had removed both in this case because he wished to remove entire the whole lymph tract.

Mr. LOUIS C. RIVETT showed a foreign body which had been removed from the lumen of the small intestine ten years after he had performed Cæsarean section. Convalescence had been delayed, the patient stated that she had not felt well since then, but she had only recently consulted her doctor. On examination a mass was found in the upper abdomen. At an exploratory operation the intestines were found to be matted together and considerable anastomosis had occurred. A foreign body found within the lumen of the matted intestines was removed through a hole which was sutured and drained. The patient made a good recovery and afterwards only complained of slight diarrhœa. The foreign body which Mr. Rivett had in his own keeping proved to be extensive fæcal concretions round a large gall-stone.

POST-GRADUATE WORK IN BERLIN.—International medical post-graduate courses are to be held in Berlin on the following subjects: internal medicine (Feb. 29th to March 5th); occupation and disease (March 7th to 14th); recent results of scientific research and their employment in obstetrics and gynæcology (March 14th to 19th); surgery (April 4th to 9th); and practical progress in X ray diagnosis and treatment (April 10th to 17th). Particulars of these and of the regular courses may be had from the information bureau of the Kaiserin Friedrich-Haus, Luisenplatz, 2, Berlin, N.W.6.

TUBERCULOSIS ASSOCIATION.

AT a meeting of the Tuberculosis Association on Jan. 15th a discussion took place on the

Psychotherapeutic Treatment of Tuberculous Patients.

Dr. S. VERE PEARSON, opening the discussion, said that he, in dealing with smaller numbers of patients than many of the physicians present, probably had the advantage of being able to devote more individual attention to the patients under his care; and hence it was probable that his patients were more frequently able to unburden their troubles and worries than would be possible in larger institutions. This mere unburdening was often of definite therapeutic value, and anything like psycho-analysis was very seldom necessary. All experienced sanatorium physicians knew how important it was to have a constant stream of mental encouragement playing upon the mind of the patient, this, in conjunction with good environment and proper treatment of the physical condition, being usually sufficient to bring about satisfactory improvement. In considering the pathogenesis of tuberculosis he believed that too much emphasis was laid upon infection by the tubercle bacillus and too little upon the psychological influences involved. In order to get a patient well they had to take into account all the ætiological factors concerned. It was necessary to recognise all the conditions which had wrought a "discord of the elements within the body," otherwise harmony and health could not be brought about. A realisation of these factors was equally necessary for diagnosis, prognosis, and treatment. Unless the psychological condition of a patient was taken into account, mistakes in diagnosis were bound to occur. It had been said that "phthisis *always* had an origin in discouragement," and although this might be only partially true they had to remember the possibility of a "psychological flight into illness." It was important for the physician in charge of a case at least to bear in mind the possibility of pulmonary tuberculosis not being the cause of the lapse from health, or of its being only one of the causes and perhaps, even in a case with markedly abnormal physical signs in the chest, one of comparatively minor importance.

The Mind in Tubercle.

Dr. ANDREW MORLAND (Mundesley Sanatorium) followed with a paper on this subject, which is published in full on p. 176 of this issue.

Dr. LEONARD F. BROWNE, dealing with the psychotherapeutic treatment of tuberculous patients, pointed out that tuberculosis being a chronic disease should be viewed from the psychotherapeutic aspect just as in the case of any other chronic toxic disease. While psychotherapy could not supersede physical treatment, it could reinforce it admirably in certain directions. The patient's attitude to life would make an enormous difference to his powers of resistance. Upon admission to the sanatorium some routine psychological examination should be made, so that the physician might get a picture of the type of personality with which he was dealing. Information as to the patient's heredity and family environment should be acquired. Reaction to former illnesses was of importance, and full particulars should be obtained of the patient's sexual history, attention being paid to any indications of arrested or warped development. The question of anxiety should be gone into, and inquiry made as to the patient's ability to adjust difficulties in his environment. In the very first interview the doctor would have the opportunity of establishing that relationship with the patient which was so valuable a therapeutic asset. The importance of the personal factor was being more and more recognised in industry, in politics, and in international relations. It was no less important in the sanatorium, and the personality of the physician played a large part in the treatment of the disease. In the long treatment which tuberculosis so often required, the relations between the doctor and his patient became very intimate. There was probably no disease which called for higher personal qualities in the medical man who treated it than tuberculosis. A strong personality, wide sympathy and understanding, approachableness, infinite tact and discretion, a willingness to discuss problems, and a sense of humour were essential qualities in dealing with the varied temperaments and mental outlook of patients suffering from this disease. The method of suggestion or persuasion was of value in dealing with the general attitude of the patient to his disease and in overcoming certain troublesome symptoms which might arise during its course, such as insomnia, cough, or anorexia. In other cases, however, patients suffering from such conditions as anxiety states or conversion hysteria—which might in themselves have paved the way for the tuberculous infection—would require analytical treatment, although it would always be a question whether any given case was suitable to undergo the strain of analysis, and the advantage of mental improvement would have to be weighed against the possibility of physical deterioration. In conclusion the speaker emphasised the importance of treating the personality of the patient. His individuality should never be lost sight of; his mental attitude should be studied and taken into account in the doctor's dealings with him. It would be an immense help for the staff of every sanatorium to include a physician with some knowledge of psychotherapy so that special treatment could be provided when necessary. In any case, for any doctor dealing with tuberculous patients a knowledge of the mental mechanisms would enable him to deal with the patient's reactions on the spot and incidentally would greatly increase the interest of his work.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this society on Jan. 8th, with Dr. H. H. MILLS, the President, in the chair, wa devoted to a discussion on the

Treatment of Carcinoma.

Mr. MALCOLM DONALDSON pleaded for the setting up of diagnostic centres for cancer. It might b suggested that this would increase the number o neurasthenics, but he personally believed that th more malignant disease was talked about the les would people be frightened of it. Centres for diagnosis should be established all over the country, bu the treatment centres, on the other hand, ought to b few and concentrated. If advance was to be made i treatment the cases must be brought to places wher special team-work could be undertaken. After treatment the patients must be seen at least once a mont in the first year, and must report three or four time a year for the rest of their lives. Going on to speak o therapeutic methods, Mr. Donaldson said that th

majority of gynæcologists now—certainly in
r countries, and increasingly in this country—
ved that radiotherapy was preferable to surgery
ie treatment of cancer of the cervix. In cancer of
body of the uterus surgery undoubtedly showed
er results than radiotherapy. though the latter
ht prolong the patient's life in cases unsuitable
operation. Carcinoma of the vagina should be
ted by radium; malignant disease of the ovary
om gave rise to symptoms before it was past all
e of relief by operation.

r. A. Piney thought that the problem of the
tment of cancer was ultimately a problem of
motherapeutics. Work had lately been done on
injection of various colloidal dyestuffs, which
eared to be stored in the tumour cells more than
the normal tissue cells, and attempts had been
le to introduce solutions of heavy metals with the
that the tumour might then be better treated
h X rays. None of these methods as yet had
ved successful, even in experimental animals, but
y pointed the way to ultimate rational treatment
the malignant cell. It appeared to him that at
sent surgery must inevitably be of enormous
ortance, for removal of tumour cells must be
ferable to destruction in situ, in view of the possi-
ty that some of them might receive a stimulating
wth of rays. Tumour cells sometimes grew fast
en their neighbours had been destroyed.

Ir. Duncan Fitzwilliams declared that the
provement of results during the last 40 years was
solely to early diagnosis. and not in the least to
reased range of operation. Nowadays the young
ctitioner who saw a tumour realised that it should
regarded as malignant until it was proved innocent,
d that the onus of proof was on himself. Until this
s recognised no advance would be made. A good
l could be done by educating the lay public not to
ore bodily ailments of which they knew nothing,
d to go to their doctor and get advice. The
nericans, who were untrammelled by the traditions
ich bound us, had instituted "cancer weeks,"
ring which it was a point of honour for every
rson in the town to go to his medical practi-
ner and be examined thoroughly; if he could
t afford a fee, payment was made by the local
ncer committee.

Sir J. Dundas-Grant was convinced that where
malignant disease was removable it ought to be
moved. When he was in general practice the cervix
eri used to be removed, and in many cases the cure
as permanent. He believed in the combination of
rgery and radiotherapy, and that this would be
ore and more developed.

Mr. J. F. McCann said that the lesson of occupa-
onal cancers was being ignored. These could. almost
ithout exception. be prevented by taking the
ecessary precautions. In this matter we suffered a
reat deal from the tyranny of pathology. Most
eople now believed that cancer was in the beginning
local disease—an idea that had been fostered through
boratory experiments. But he held the contrary
pinion. He preferred to make his judgment on the
uman, and had found that in very early cases there
as always a certain departure from health—the
rimary cachexia of former writers. In some cases
t might be slight and escape notice. in other cases it
as extreme. It had to be remembered also that
ancer was primarily a disease of middle or advanced
ge.

Dr. S. Monckton Copeman spoke as one who had been a member of the committee on cancer set up by the Ministry of Health. From the investigations of that committee it was apparent that about 50 per cent. of cases of cancer never underwent treatment of any kind whatsoever. He mentioned favourably the chemotherapeutic method which depended upon the use of fluorescein irradiated by X rays or radium.—Dr. J. E. A. Lynham pleaded for a medical rather than a surgical conception of radiology in this disease.—Dr. Rickard Lloyd rebutted comments on the general practitioner's inability to diagnose cancer.—The President mentioned the presence of tumours apparently carcinomatous in very aged people. He had one case in mind in a woman of 95, who to his knowledge had had a huge abdominal swelling for several years; but her primæ viæ were open, and she was apparently well.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

A meeting of this section was held on Jan. 8th, with Dr. J. Lait, in the absence of the President, in the chair. Mr. F. J. Henry showed for Sir William Wheeler a

Solitary Serous Cyst of the Kidney.

The specimen had been removed from a woman aged 57. She had complained of intermittent attacks of painless hæmaturia, and presented a smooth mobile non-tender enlargement of the right kidney. A pre-operative diagnosis of hypernephroma had been made, but at operation a large solitary cyst was found in the upper pole of the right kidney. This cyst was removed by conservative resection. a small layer of renal tissue having been shaved off. The patient made an uneventful recovery.

The Chairman said he did not think that cysts of the kidney were as rare as they were supposed to be. He was interested to hear that urea was found in the cystic fluid, for this was a very uncommon finding.

Mr. Henry, in replying, said that Sir John Thomson-Walker regarded solitary cysts of the kidney as extremely rare. McKim and Smith in America had reported 120 cases, two of which were from Dublin. In their cases hæmaturia was a very unusual feature. They called attention to the necessity of distinguishing between true solitary cysts of the kidney and perirenal cysts.

Endothelioma of the Pleura.

Dr. J. Lewis showed a specimen from a woman, aged 41, who had suffered for some months from pain in the left side of the chest. She had paroxysmal pains which radiated down the left arm. She developed a serous pleural effusion which later became hæmorrhagic. Only one enlarged gland could be found, situated behind the left clavicle, and it was removed for histological examination. The left pupil was dilated. Post-mortem examination revealed a thickened pleura and a hæmorrhagic effusion. There were plaques of endothelioma studded over the parietal pleura and on its diaphragmatic surface. There were also some plaques on the pericardium. Secondary deposits were found in the liver, kidneys, and mediastinal glands. Histologically the tumour was a typical endothelioma.

TUBERCULOSIS ASSOCIATION.

AT a meeting of the Tuberculosis Association on Jan. 15th a discussion took place on the

Psychotherapeutic Treatment of Tuberculous Patients.

Dr. S. VERE PEARSON, opening the discussion, said that he, in dealing with smaller numbers of patients than many of the physicians present, probably had the advantage of being able to devote more individual attention to the patients under his care; and hence it was probable that his patients were more frequently able to unburden their troubles and worries than would be possible in larger institutions. This mere unburdening was often of definite therapeutic value, and anything like psycho-analysis was very seldom necessary. All experienced sanatorium physicians knew how important it was to have a constant stream of mental encouragement playing upon the mind of the patient, this, in conjunction with good environment and proper treatment of the physical condition, being usually sufficient to bring about satisfactory improvement. In considering the pathogenesis of tuberculosis he believed that too much emphasis was laid upon infection by the tubercle bacillus and too little upon the psychological influences involved. In order to get a patient well they had to take into account all the ætiological factors concerned. It was necessary to recognise all the conditions which had wrought a "discord of the elements within the body," otherwise harmony and health could not be brought about. A realisation of these factors was equally necessary for diagnosis, prognosis, and treatment. Unless the psychological condition of a patient was taken into account, mistakes in diagnosis were bound to occur. It had been said that "phthisis *always* had an origin in discouragement," and although this might be only partially true they had to remember the possibility of a "psychological flight into illness." It was important for the physician in charge of a case at least to bear in mind the possibility of pulmonary tuberculosis not being the cause of the lapse from health, or of its being only one of the causes and perhaps, even in a case with markedly abnormal physical signs in the chest, one of comparatively minor importance.

The Mind in Tubercle.

Dr. ANDREW MORLAND (Mundesley Sanatorium) followed with a paper on this subject, which is published in full on p. 176 of this issue.

Dr. LEONARD F. BROWNE, dealing with the psychotherapeutic treatment of tuberculous patients, pointed out that tuberculosis being a chronic disease should be viewed from the psychotherapeutic aspect just as in the case of any other chronic toxic disease. While psychotherapy could not supersede physical treatment, it could reinforce it admirably in certain directions. The patient's attitude to life would make an enormous difference to his powers of resistance. Upon admission to the sanatorium some routine psychological examination should be made, so that the physician might get a picture of the type of personality with which he was dealing. Information as to the patient's heredity and family environment should be acquired. Reaction to former illnesses was of importance, and full particulars should be obtained of the patient's sexual history, attention being paid to any indications of arrested or warped development. The question of anxiety should be gone into, and inquiry made as to the patient's ability to adjust difficulties in his envir ment. In the very first interview the doctor wo have the opportunity of establishing that relations with the patient which was so valuable a therape asset. The importance of the personal factor being more and more recognised in industry, in polit and in international relations. It was no important in the sanatorium, and the personality the physician played a large part in the treatm of the disease. In the long treatment wl tuberculosis so often required, the relations betw the doctor and his patient became very intim There was probably no disease which called higher personal qualities in the medical man treated it than tuberculosis. A strong personal wide sympathy and understanding, approachablen infinite tact and discretion, a willingness to dis problems, and a sense of humour were essen qualities in dealing with the varied temperam and mental outlook of patients suffering from disease. The method of suggestion or persua was of value in dealing with the general attit of the patient to his disease and in overcoming cer troublesome symptoms which might arise during course, such as insomnia, cough, or anorexia. In ot cases, however, patients suffering from such co tions as anxiety states or conversion hysteria—wl might in themselves have paved the way for tuberculous infection—would require analytical tr ment, although it would always be a question whe any given case was suitable to undergo the strai analysis, and the advantage of mental improven would have to be weighed against the possibilit physical deterioration. In conclusion the spe emphasised the importance of treating the persona of the patient. His individuality should never lost sight of; his mental attitude should be stu and taken into account in the doctor's dealings him. It would be an immense help for the stai every sanatorium to include a physician with s knowledge of psychotherapy so that special tr ment could be provided when necessary. In any c for any doctor dealing with tuberculous pati a knowledge of the mental mechanisms would en him to deal with the patient's reactions on the s and incidentally would greatly increase the inte of his work.

WEST LONDON MEDICO-CHIRURGIC SOCIETY.

A MEETING of this society on Jan. 8th, Dr. H. H. MILLS, the President, in the chair, devoted to a discussion on the

Treatment of Carcinoma.

Mr. MALCOLM DONALDSON pleaded for the sett up of diagnostic centres for cancer. It might suggested that this would increase the numbe neurasthenics, but he personally believed that more malignant disease was talked about the would people be frightened of it. Centres for d nosis should be established all over the country, the treatment centres, on the other hand, ought t few and concentrated. If advance was to be mad treatment the cases must be brought to places w special team-work could be undertaken. After tr ment the patients must be seen at least once a mo in the first year, and must report three or four ti a year for the rest of their lives. Going on to spea therapeutic methods, Mr. Donaldson said that st majority of gynæcologists now—certainly in er countries, and increasingly in this country—ieved that radiotherapy was preferable to surgery the treatment of cancer of the cervix. In cancer of body of the uterus surgery undoubtedly showed tter results than radiotherapy, though the latter ght prolong the patient's life in cases unsuitable operation. Carcinoma of the vagina should be ated by radium; malignant disease of the ovary dom gave rise to symptoms before it was past all pe of relief by operation.

Dr. A. Piney thought that the problem of the atment of cancer was ultimately a problem of emotherapeutics. Work had lately been done on e injection of various colloidal dyestuffs, which peared to be stored in the tumour cells more than the normal tissue cells, and attempts had been ade to introduce solutions of heavy metals with the ea that the tumour might then be better treated ith X rays. None of these methods as yet had oved successful, even in experimental animals, but ey pointed the way to ultimate rational treatment the malignant cell. It appeared to him that at esent surgery must inevitably be of enormous portance, for removal of tumour cells must be eferable to destruction in situ, in view of the possi-lity that some of them might receive a stimulating owth of rays. Tumour cells sometimes grew fast hen their neighbours had been destroyed.

Mr. Duncan Fitzwilliams declared that the nprovement of results during the last 40 years was ue solely to early diagnosis, and not in the least to icreased range of operation. Nowadays the young ractitioner who saw a tumour realised that it should e regarded as malignant until it was proved innocent, nd that the onus of proof was on himself. Until this as recognised no advance would be made. A good eal could be done by educating the lay public not to nore bodily ailments of which they knew nothing, nd to go to their doctor and get advice. The mericans, who were untrammelled by the traditions hich bound us, had instituted "cancer weeks," uring which it was a point of honour for every erson in the town to go to his medical practi-ioner and be examined thoroughly; if he could ot afford a fee, payment was made by the local ancer committee.

Sir J. Dundas-Grant was convinced that where malignant disease was removable it ought to be emoved. When he was in general practice the cervix teri used to be removed, and in many cases the cure was permanent. He believed in the combination of urgery and radiotherapy, and that this would be more and more developed.

Mr. J. F. McCann said that the lesson of occupational cancers was being ignored. These could, almost without exception, be prevented by taking the necessary precautions. In this matter we suffered a great deal from the tyranny of pathology. Most people now believed that cancer was in the beginning a local disease—an idea that had been fostered through laboratory experiments. But he held the contrary opinion. He preferred to make his judgment on the human, and had found that in very early cases there was always a certain departure from health—the primary cachexia of former writers. In some cases it might be slight and escape notice, in other cases it was extreme. It had to be remembered also that cancer was primarily a disease of middle or advanced age.

Dr. S. Monckton Copeman spoke as one who had been a member of the committee on cancer set up by the Ministry of Health. From the investigations of that committee it was apparent that about 50 per cent. of cases of cancer never underwent treatment of any kind whatsoever. He mentioned favourably the chemotherapeutic method which depended upon the use of fluorescein irradiated by X rays or radium.—Dr. J. E. A. Lynham pleaded for a medical rather than a surgical conception of radiology in this disease.—Dr. Rickard Lloyd rebutted comments on the general practitioner's inability to diagnose cancer.—The President mentioned the presence of tumours apparently carcinomatous in very aged people. He had one case in mind in a woman of 95, who to his knowledge had had a huge abdominal swelling for several years; but her primæ viæ were open, and she was apparently well.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

A meeting of this section was held on Jan. 8th, with Dr. J. Lait, in the absence of the President, in the chair. Mr. F. J. Henry showed for Sir William Wheeler a

Solitary Serous Cyst of the Kidney.

The specimen had been removed from a woman aged 57. She had complained of intermittent attacks of painless hæmaturia, and presented a smooth mobile non-tender enlargement of the right kidney. A pre-operative diagnosis of hypernephroma had been made, but at operation a large solitary cyst was found in the upper pole of the right kidney. This cyst was removed by conservative resection, a small layer of renal tissue having been shaved off. The patient made an uneventful recovery.

The Chairman said he did not think that cysts of the kidney were as rare as they were supposed to be. He was interested to hear that urea was found in the cystic fluid, for this was a very uncommon finding.

Mr. Henry, in replying, said that Sir John Thomson-Walker regarded solitary cysts of the kidney as extremely rare. McKim and Smith in America had reported 120 cases, two of which were from Dublin. In their cases hæmaturia was a very unusual feature. They called attention to the necessity of distinguishing between true solitary cysts of the kidney and perirenal cysts.

Endothelioma of the Pleura.

Dr. J. Lewis showed a specimen from a woman, aged 41, who had suffered for some months from pain in the left side of the chest. She had paroxysmal pains which radiated down the left arm. She developed a serous pleural effusion which later became hæmorrhagic. Only one enlarged gland could be found, situated behind the left clavicle, and it was removed for histological examination. The left pupil was dilated. Post-mortem examination revealed a thickened pleura and a hæmorrhagic effusion. There were plaques of endothelioma studded over the parietal pleura and on its diaphragmatic surface. There were also some plaques on the pericardium. Secondary deposits were found in the liver, kidneys, and mediastinal glands. Histologically the tumour was a typical endothelioma.

REVIEWS AND NOTICES OF BOOKS

Intracranial Pyogenic Diseases.

By A. LOGAN TURNER, M.D., F.R.C.S. Edin., and F. ESMOND REYNOLDS, M.D., M.R.C.P. Edin. London: Oliver and Boyd. 1931. Pp. 271. 12*s*. 6*d*.

SOME nine years ago Mr. Logan Turner and Dr. Esmond Reynolds began to investigate the pathways by which infection spreads from the face, nasal, and paranasal air cavities into the intracranial chamber. and this monograph gives a full account of their work. They have carefully studied 55 cases, mostly fatal, of intracranial infection following such conditions as ethmoidal and sphenoidal suppuration, and in a considerable number of these they have conducted exhaustive morbid anatomical investigations along special lines. Their method has been to remove at necropsy a large part of the floor of the anterior and middle cranial fossæ and then to examine in serial sections the upper part of the nose, the air sinuses, orbits, base of the skull, cavernous sinuses, and overlying membranes. In spite of the frequency of fatal intracranial infections from these sources the authors have only been able to find in the literature eight cases in which adequate investigations of this nature have hitherto been made.

As a result of their work Mr. Logan Turner and Dr. Reynolds conclude that in their 55 cases infection spread to the intracranial cavity by the venous blood stream in 19 cases, by direct extension through bone and dura in 20 cases, by a combination of these two routes in eight cases, and along the perineural sheaths of the olfactory nerves in four cases. In four cases the pathway of infection could not be determined. Selected cases are described in full to illustrate the various paths of infection, and there is an excellent account of the venous and other connexions between the face, nose, and paranasal air cavities, and the intracranial chamber. The authors show effectually that there is no lymphatic pathway from the nose to the cranium.

Septic thrombosis of the cavernous sinuses occurred in 22 cases, especially after infection of the sphenoidal air cavity. The authors describe fully the symptoms of this condition, and as far as possible correlate the symptoms with the pathological changes that their studies revealed. Their researches show that it is not possible to interpret all the symptoms conclusively, because most fatal cases show infection of more than one intracranial structure; for example, there are intimate venous connexions between the cavernous sinus and the meninges, and suppuration in the cavernous sinus is likely soon to be followed by purulent pachy- and leptomeningitis. Brain abscess is relatively uncommon in their series. In describing leakage of brain abscess no reference is made to leakage into the lateral ventricles, probably the most common method of spread of abscess of the cerebral hemisphere.

The book contains important observations about intracranial infection following operation on the paranasal air cavities, a subject on which there has hitherto been very little accurate information. In 45 cases in which the primary focus of infection was in the paranasal air cavities, intracranial infection occurred spontaneously in 25, while in 20 it developed shortly after operation on one or more of the diseased air cavities. Operation on the ethmoidal cells of the type introduced by Sluder appears to be particularly dangerous in this respect, and may result in spread of infection either by producing fracture of the floor of the anterior fossa, laceration of the olfactory perineural sheaths, or in some instances by setting up acute osteomyelitis of the cranial and facial bones. Alarming as they are, complications of this sort occurred in only about 1 per cent. of a large series of operations on the paranasal air cavities at the Royal Infirmary of Edinburgh, and most often in those cases in which more than one paranasal air cavity contained pus and only one was drained by operation. It is possible that the liability to intracranial infection after paranasal operations may be considerably diminished by more free exposure of the infected areas.

This beautifully produced monograph follows the best traditions of Scottish medicine and is fit to b placed alongside the classic work of Macewen o intracranial infections. There is only one criticism of importance: that the authors have been unduly cautious in drawing the conclusions of a clinica nature that their work entitles them to make, especiall conclusions as to treatment. The reader is lef wondering what their views about surgical intervention in chronic paranasal infections really are; an whether this work has promoted the clinical recognitio of those cases that are likely to be followed by fat intracranial infection if operation is undertake There is no one more entitled to propound such vie than Mr. Logan Turner, and no one from whom t general medical reader would more welcome them.

The Pathology of Diabetes Mellitus.

By SHIELDS WARREN, M.D., Pathologist to the N England Deaconess Hospital, and the Huntingd Memorial Hospital, Boston; Instructor in Path logy in the Harvard Medical School, Bost Massachusetts. London: Baillière, Tindall a Cox. Pp. 212. 21*s*.

THIS monograph is important inasmuch as contains a full and exhaustive account of the pat logical lesions found in all the organs of the body patients who had diabetes mellitus during life. Rat more than one third of the monograph is devoted t description of the islands of Langerhans, together w the proof that the β cells supply insulin to the bo The evidence for the pathological changes is set fully, and Dr. Warren points out that, although β cells undoubtedly secrete the insulin, the chan which occur in the islands in patients dying of diab mellitus by no means afford conclusive proof of t The most typical change is hyalinisation, wh destroys or separates the epithelial cells from blood-supply. The diabetes which is associated w hyalinisation of the islands is apt to be mild, a even in patients over 40 years of age, a fair numbe cases are described in which hyalinisation exis without the occurrence of diabetes.

In the older patients fibrosis tends to occur as as hyalinisation. Lymphocytic infiltration in about the islands has been observed, especially severe cases of short duration. Much importanc attached by Allen to hydropic degeneration, a result of his observations on partially depancreati animals. This change appears to be due not to result of injury but to excessive functional strain, its appearance is thus a sign that an increased str is being put on the β cells. Hydropic degeneratio always present in patients dying from diabetes, , moreover, post-mortem changes may cause very ilar appearances. One of the difficulties of ssing the importance of these changes lies in the that in 69 out of 259 cases the pancreas showed nds which appeared quite normal.

he distribution of glycogen in the body of normal ients, and in diabetics who have been treated with without insulin. is of great interest. An increase lycogen in the epithelium of Henle's loops is the t definite anatomical finding in active diabetes litus, but the heart muscle also contains more ogen, and the liver cells have vacuoles which are d with it. The skin of the diabetic, on the other d, contains very little glycogen. Dr. Warren deals y with arterio-sclerosis and gangrene in diabetics. tistical evidence that a premature development of rio-sclerosis occurs among the diabetic patients is clusive. Although this condition is especially mon among the elderly patients, it occurs also ong the young. Seven out of 23 patients under years in the series showed definite changes in arteries when X rayed. Arterio-sclerosis was the ual cause of death in 72 out of 300 cases. In 31 these a coronary thrombosis was present, and in gangrene of an extremity. The factor or factors ich may be responsible for the premature development of the arterio-sclerosis in diabetics are discussed. e view is put forward tentatively that it is in some y due to the initial period of hyperglycæmia which ises the damage, and is followed up by the hyper- lesterinæmia arising as the result of a diet con- ning too much fat and too little carbohydrate. The pendix contains an analysis of the cause of death 1294 diabetics.

The book is well indexed and provides information high value to all interested in the subject.

e Cardiac Cycle.

By HARRINGTON SAINSBURY, O.B.E., M.D., F.R.C.P., Consulting Physician to Royal Free Hospital, Victoria Park Hospital for Diseases of the Chest, and Royal National Hospital, Ventnor. Bristol: John Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1931. Pp. 79. 5s.

IN his small monograph on the cardiac cycle r. Harrington Sainsbury advances the hypothesis at the pulse wave is produced not by the ejection of ood from the left ventricle into the aorta, but by the ipact of the ventricular contents against the closed milunar valve during the isometric phase of ven- icular systole. This hypothesis is so entirely compatible with the known experimental facts, iat one cannot help wondering whether his meaning ay not have been misunderstood. His argument ppears to be that the force exerted during systole gainst the ventricular surface of the closed aortic alve must produce an equivalent pressure change in ie aorta which will be transmitted along the arteries the periphery, and that this pressure change onstitutes the pulse. That there is a slight rise of ressure in the aorta corresponding in time to the rise f pressure in the ventricle prior to the opening of the ortic valve is well known; but this rise is insigni- icant as compared with the rise of pressure which ccompanies ventricular ejection. In order to upset he current teaching that the percussion wave of the ulse is initiated by ventricular ejection, it would be ecessary to bring forward experimental evidence to rove that the time relations of the pressure changes in the heart and aorta observed by previous workers are incorrect. Dr. Sainsbury does not suggest that this is so, nor does he bring forward any new experimental evidence in support of his views. His argument is purely philosophical, and if we have understood it correctly, it is unsound.

The Lungs and Early Stages of Tuberculosis.

By LAWRASON BROWN, M.D., Consultant, Foudeau Sanatorium; and FRED H. HEISE, M.D., Medical Director of the Sanatorium. London: D. Appleton and Co. 1931. Pp. 151. 5s.

THE object of this book was to present the subject of tuberculosis "from a standpoint that can be readily understood by the layman," and it has been achieved. Members of public health committees, health visitors, nurses and, indeed, all who are interested in preventing disease and in safeguarding the health of the young, will find in this book all they require for an understanding of the problem of tuberculosis, whether regarded as a disease of the individual or as a menace to the community. The chapters on the early symptoms of tuberculosis and the means which should be adopted for its detection might be read with advantage by all medical students. And medical practitioners might profit from the reminder that in a doubtful case no examination of the chest is complete which does not include a radiogram of the best obtainable quality, interpreted by someone who has had special experience in chest radiography.

Fractures.

By MEURICE SINCLAIR, C.M.G., M.B., B.Ch. Edin., Major, R.A.M.C. Ret., Specialist in Fractures and Orthopædic Surgery to St. James' and Paddington Hospitals, London. With an introduction by Sir ROBERT JONES, Bt., K.B.E., C.B., F.R.C.S. London: Constable and Co., Ltd. 1931. Pp. 550. 24s.

THOSE who were familiar with Major Sinclair's work during the war at No. 8 Stationary Hospital know him as a master of technique and painstaking care, whose results in the treatment of war fractures were an inspiration to all who came in contact with them. We welcome an account in book form of his principles and methods of treatment. The first part of the monograph is devoted to a consideration of principle and the second to detailed methods of treatment of individual fractures, and both are clear, well written, and full of interest from beginning to end. There is a certain air of dogmatism which might be irritating to those who do not discern in it the mark of the enthusiast; the insistence on attaching the author's name to splints and apparatus might equally seem exaggerated to a generation which does not remember the difficulties which any original work had to overcome during the war before gaining recognition. No one should allow any such minor points to lead them to neglect this work. It should be studied by every one who is concerned with fracture cases, and should do a good deal to remove the reproach that the lessons so slow and painfully learnt during the war are being forgotten with indecent haste. Sir Robert Jones says in his introduction that the author's services at the front were memorable and never received the recognition they deserved. This book should do much to secure for him appreciation of his mastery of the technique of the treatment of fractures.

Radiology in Relation to Medical Jurisprudence.

By S. Gilbert Scott, M.R.C.S., L.R.C.P., D.M.R.E. Camb., Consulting Radiologist to the London Hospital and to Queen Alexandra Military Hospital, Millbank. London : Cassell and Co., Ltd. 1931. Pp. 65. 7*s.* 6*d.*

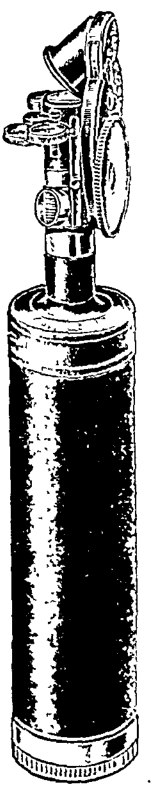
This small volume aims at assisting radiologists in medico-legal cases. It is based on the wealth of material that has passed through the author's hands in the course of 22 years, during which time he has been in charge of the radiological department of the London Hospital. With such a vast experience behind him Dr. Gilbert Scott might well have written a rather more ambitious work. It only contains 65 pages, and a quarter of these are devoted to an extremely elementary statement of the fundamentals of radiology, written for the benefit of the legal profession.

The author confines himself to the osseous system, and says that he has made no attempt to describe all the variations from the normal nor every one of the fallacies and pitfalls which beset radiologists in general medicine. Hence the work is somewhat incomplete even in the limited sphere that the author has chosen. One omission should be rectified in a future edition. Dr. Gilbert Scott, while describing the usual spinal conditions, fails to emphasise the fact that the absence of radiographically demonstrable bony injury does not necessarily mean that the patient has not received an injury and that this injury is real. In the courts stress is laid on the positive evidence of an injury as shown by the radiographs, and compensation results as a matter of course, even though actual disability may be slight. The absence of radiographic evidence of injury prejudices a man's claim for compensation and many cases of miscarriage of justice result. It is the radiologist's duty in such cases to emphasise the limitations of his technique and to stress the fact that the decision in such a case must not be influenced by the absence of changes that can be detected radiographically. This is an important point, especially in spinal cases. The 25 radiographic illustrations are well chosen and excellently reproduced.

NEW INVENTIONS

AN ELECTRIC OPHTHALMOSCOPE.

The optical part of this ophthalmoscope was shown to the Ophthalmological Society of Great Britain and Ireland in 1904, and a description of the mechanism was given in The Lancet (1905, ii., 28). Recently, Messrs. Rayner, of Bond-street, London, who had acquired the original patterns, asked me if I would supervise the adaptation of the original reflecting ophthalmoscope to a self-contained electric fitting.



The new model has certain advantages. The attachment of a battery handle to a magazine ophthalmoscope, such as Couper's or Morton's adaptation thereof, produces an inconveniently long instrument. This new ophthalmoscope, although it has a range of 70 dioptres, from +30 to −39 in steps of 1 dioptre, is no longer than a May's ophthalmoscope with its small range of lenses.

The range of 70 dioptres is produced by 15 actual lenses. The mechanism which I adapted to this ophthalmoscope was invented by Harding, an engineer of Leeds, about 1870, and is thoroughly reliable. It has been extensively used in speed indicators, meters, and stop-watches. The first of these ophthalmoscopes, made in 1903, I have used regularly since then; it has never got out of order.

There are two lens discs. These overlap at the sight hole. The larger, or "units" disc has ten holes, one blank and nine glazed from −1 to −9 dioptres. At one point on the rim of this disc there is a finger-like projection. The smaller, or "tens" disc has seven holes, one blank the others glazed +10, +20, +30, −30, −20, −10 dioptres. On one face of this "tens" disc is a spur wheel of seven teeth. As the driving wheel is turned past 9 dioptres, the "finger" of the "units" disc automatically engages with the spur wheel and moves the "tens" disc one place either way, according to the movement of the driving wheel. The edge of the "tens" disc is milled, and one part is exposed through the edge of the body of the instrument, so that it can be turned directly to bring a strong convex lens to the sight *hole.*

In providing an electrical attachment, the aim has been to secure the widest, most variable, and most stable range of illumination. The battery supplying the lamp is a standard "Ever Ready" pattern No. 1829. It will keep the lamp burning continuously for over 13 hours, stil giving sufficient illumination for examination of the fundus continuous discharge is a severe test. The lamp is gas filled, and has a small coil filament.

A focusing lens controlled by an external collar regulat the beam from the instrument. When the collar is at th bottom position, a slightly diverging beam giving th effect of a plano mirror retinoscope is produced. As th collar is moved upwards the beam becomes convergin until a very short focus is reached, after which the bea becomes increasingly divergent. At a distant of one inc the illumination varies from considerably over 100 fo candles with the filament almost focused, to about 30 wi the most widely divergent beam. By using the resistan in the circuit the divergent beam can be reduced to 2 fo candles. Great care has been taken to ensure a fine contr of the focusing movement.

Four cells are hinged to the lamp tube and can be int posed between the light and the mirror. They conta filters, red, green, and "daylight," and a diaphragm wit small central hole. These screens can be readily broug into use and are very serviceable.

The instrument is excellent for retinoscopy at t distance of one metre, either with the white or r light. It has proved itself to be a first-rate emergen operation lamp, since it will throw a beam of paral rays of about 20 foot candles from a distance 6 inches which will illuminate the eye and lids; a as the ophthalmoscope is held horizontally above t eye it is easy to keep it in position and out of t operator's way.

Finally, mention may be made of the covering the handle which contains the battery. *This* coated with an even layer of fine sand which gives perfectly easy grip. The instrument can therefo be held easily with the fingers with *no* sense of ri of slipping and without the damp chilly feeli which comes to leather covered handles after mu usage.

The instrument is packed in a case with an arrang ment which allows of its immediate extraction wh it is required.

N. Bishop Harman, F.R.C.S. Eng.

de KUYPER'S

HOLLANDS

Distilled from genuine malt liquor with the Juniper berry added. The advantage gained by distilling the berry with the spirit is the production of a preparation of Oleum Juniperi, mellow and free from irritating properties.

Oleum Juniperi is official in the British Pharmacopœia, and is described as carminative, anti-spasmodic, and a stimulating diuretic.

In this form, therefore, the oil of Juniper can be safely taken with regularity.

Distilled by the same family for 236 years.

THE CERTIFICATION OF BLINDNESS.[1]

COMMITTEE was appointed in November, 1930, the Union of Counties Associations for the nd to report on the problems of the prevention blindness. The committee, which was given wer to coöpt persons to its body, availed themves freely of the permission, and the result is a animous report of extensive utility. For the nomic importance of blindness from the national int of view has been pressing since 1919, when ants in aid of the welfare of the blind were first ide by the Ministry of Health. Pensions were en granted to all persons over 50 years of age o were "so blind as to be unable to perform y work for which eyesight is essential," while 1920 the Blind Persons Act was passed which t these grants and pensions on a permanent sis. Grants through local authorities are now ade at rates varying from 15*s.* to 27*s.* 6*d.* a week, d pensions to the blind who are over 50 years of ge are provided by the State at the rate of 10*s.* week. But unfortunately, even now, no uniform ystem of registration and certification of the lind is in force in England. The Ministry of Health ave been endeavouring for a long period to ersuade the local authorities to adopt a registraion clause providing for the certification of the lind by a medical practitioner with special xperience in ophthalmology, but in the summer f 1931 only 52 per cent. of the counties and ounty boroughs of this country had either ormally or informally adopted this proposal. Further, many of these local authorities only fell n with the process of registration in respect of ases which were considered doubtful, and that is a matter where, except in cases where both eyes have been excised, it is unwise to leave decisions to the judgment of any but a skilled ophthalmologist. The committee's first recommendation, therefore, is that the employment of an ophthalmic surgeon should be made compulsory in every case before a blind person is put on the register as such. With regard to the grant of Old Age Pensions the rocedure is somewhat different, but even here here exists no guarantee that the local pension officer may not decide the claim of an applicant without ever having had the opinion of a skilled ophthalmologist.

At present it is possible for a person to be put on the blind register by the local authority and to be refused a pension by the pension authority when he attains the age of 50, and vice versa. The second recommendation of the committee is, therefore, that the procedure for certifying blindness, both for the purpose of entry in the blind register and for the granting of blind Old Age Pensions, should be unified. It must be emphasised that the actual certification of blindness may be a matter of considerable difficulty, and up till now there has certainly been a lack of uniformity in the standard required by various authorities in interpreting the phrase "so blind as to be unable to perform work for which eyesight is essential." A circular issued by the Ministry of Health, not as a rigid instruction, but as a guide to the certifying surgeon, puts a visual acuity of 3/60 as a limit under which a person may *usually* be considered blind, while those with vision 6/60 or better cannot be considered blind unless there are other visual disabilities, and more especially a greatly contracted field of vision. Concerning those with vision between 3/60 and 6/60 the circular is indefinite, and it is evidently intended that in deciding on these difficult borderland cases a good deal should be left to the discretion of the certifying surgeon. In making their recommendations as to future procedure the committee have taken as a model the system recently introduced into Scotland, after having been for a few years in actual work in Glasgow. This system provides for the examination of every case by *two* experts, so that personal idiosyncrasy may be checked. For this purpose a limited number of clinics have been organised in the chief centres, while for outlying districts special arrangements have to be made. The clinic system is being used in Scotland to secure, in addition to the certificate, a statement of the cause of blindness, and with this purpose in view a form has been drawn up on which the results of the examination have to be stated in considerable detail. The committee recommend that this system should be adopted. Stress is laid upon the necessity of stating not only the condition of the eyes which involves blindness, but also its cause. Certain detailed recommendations are made with regard to the definition of blindness, with special reference to the borderland cases in which the visual acuity lies between 3/60 and 6/60; guidance as to what degree of defect of the field should be considered as a factor is given, while the age of the patient at the time, and not when the onset of "blindness" occurs must also be taken into account. Such directions should give much needed help in his difficult task to the certifying surgeon, while leaving him with a good deal of personal responsibility. The Scottish plan of requiring every certificate to be signed by two ophthalmic surgeons when possible is therefore specially to be commended.

Besides the form of certificate of blindness applicable to adults, suggested in the report, forms are framed of two certificates for children under 16. Here, for purposes of the Education Act, the definition of blindness now in use is "too blind to be able to read the ordinary school-books used by children," and these forms of certificate are framed for two purposes. First, their employment would enable the education authorities to discriminate between children so blind that they can only be appropriately taught in a special school or class for *totally* blind children, from those who can appropriately be taught in a school or class for the *partially* blind. Secondly, these certificates would distinguish between those children who, when they attain the age of 16, are likely to be so blind as to come within the provisions of the Blind Persons Act, and those of whom this cannot be said. There is also a form of certificate meant to apply to those cases of partial blindness of a progressive character not yet blind enough to fall within the provisions of the Act but likely to become so at a later period. It is obvious that the information which these examinations and certificates are meant to elicit would be of value also in determining whether children with defective sight are more suitably educated in an ordinary school, a blind school, or a special school or class for the partially blind. It is also obvious that to obtain reliable information on all these points cases must be examined with care, knowledge, and skill. We therefore heartily commend this important report to the consideration of the authorities concerned.

MODERN HOSPITAL CONSTRUCTION.

THIS is not a time to contemplate with equanimity the demands of a community for a new hospital. In this country hospital beds are admittedly wanted, and badly wanted in many places, but, as far as possible, we must mostly rely upon modifications, annexes, and partial rebuildings and adaptations, even though the policy of providing a whole new hospital would be the best course. Indeed, it might be in the long run the more economical direction of effort, but the general financial position does not allow of the expenditure of large sums to-day in order that still larger sums may be saved later. To many, therefore, it may seem inopportune just now to call attention to the modern principles of hospital construction, but there are reasons for the other view. First, we can contemplate the ideal and learn lessons for the future without the temptation to spend; and, secondly, we can from scrutiny of the latest manners in hospital construction derive valuable lessons for procedures of renovation.

The last issue of *Nosokomeion*, published in October, 1931, contained a series of articles on modern hospital construction by leading specialists in England, America, France, Germany, and Italy. These show in a most suggestive fashion that fundamental changes in hospital planning have been taking place recently upon American models. And though the details of structure vary with the architectural tendencies of each country certain common principles have been evolving. The pavilion system which long remained the standard type is no longer followed in an invariable way. The ward units are more often placed vertically one above the other, rather than side by side as formerly. The sanitary tower is also disappearing though it had many architectural advantages. Taller buildings, smaller wards, larger windo space, and a more ample provision of balconi are among the more obvious changes noticeable i modern hospitals. They have been brought about by a desire for efficiency and economy expressed by a more compact plan and a more concentrated arrangement of the engineering services, and they take note, inter alia, of such different things as modern views on cross-infection the desire for greater privacy and comfort for the patients, and safety as evidenced in new methods of fireproof construction. In all these things no doubt the influence of American hospital planning has been a powerful factor in bringing about changes in European countries. For example, the Columbia-Presbyterian Medical Centre in New York City, an illustrated account of which was published in a special supplement to THE LANCET,[1] is echoed in France by the designs for the Hospital at *Clichy*. But in this building the balcony projection on the cantilever principles has been made a strong feature of the design, particularly on the tenth and eleventh storeys where it is continuous. These two top storeys not only form an effective horizontal line to the top of the building but provide open-air lying-space for tuberculous patients. The balcony principle has been carried a step further in another French example, the hospital at Colmar, where the terrace type of balcony has been employed in an ingenious way. The storeys are set back one behind the othe on the south side to provide balconies for th patients, but the building has only six storey making no attempt to "sky-scrape"; to emplo usefully the width of the lower floors, a series o overhangs have been built. This was mad possible by using reinforced concrete and show that in times to come the architects of hospita must take this form of building into consideratio Many of the points mentioned appear in graph illustrations and ground plans which are reproduce in this journal, but the chapter in *Nosokomei* on German hospitals is not illustrated. Th is unlucky for some of the most interesting modern hospitals have been erected in that countr But as Herr v. A. LOMMEL, the writer of the chapt points out, the present economic crisis may res in a central corridor type of plan. But it is to hoped that the small ward, facing south and openi off a north corridor, will continue in favour. Ma of the changes in hospital construction to whi attention has been drawn are well illustrated in t designs for the new Freemasons' Hospital, Ravenscourt Park, of which an excellent sket plan appeared in the *Times* on Wednesday last.

In England among the most interesting develo ments noted in the hospitals selected for not is the increased use of the type of ward in whi the beds are placed parallel with the walls, wi glazed metal screens separating the heads of t patients. Mr. C. E. ELCOCK, who is responsi for the chapter on the present position of hospi construction in this country, describes and illu trates the variation of this type which he names t verandah" ward (because no verandah is quired). with large horizontal window spaces. ie right proportion of window space to wall ace is largely a matter of opinion. but we should rselves consider it important to avoid very large ndows except towards the south. The lively erest taken in hospital planning in Europe and nerica and the evident desire for new ideas in hitecture to keep pace with progress in medical ence must be welcomed as signs of healthy tivity. But modern hospital planning has anges, almost revoluntionary in character, to be epared for. The increase in special classes of tients and the probability that sooner or later h and poor will, to an increasing extent, be ated under one roof, on some graded principles fee, demand variety and flexibility of planning. e treatment of out-patients in special departments ll affect the hospital planning of the future dically. and the need for expansion in these rections must necessitate ample open space und any new hospital buildings. With regard this point past history and present circumstances ow only too clearly the folly of producing a st-iron plan with all spaces allocated. There much to think about, and it is to be hoped that ought will be taken during the breathing space nforced upon us by poverty. The time will come ; t us be ready.

[1] THE LANCET, Jan. 5th, 1929.

COMPLICATIONS OF TONSILLECTOMY IN CHILDHOOD.

The convalescence of children after the removal tonsils and adenoids is usually uneventful, but e complications of an operation so frequently erformed must necessarily reach a considerable tal Of these, hæmorrhage, reactionary and condary. is the most common, but others also re important, as Mr. J. A. Keen [1] shows from his sperience of 9344 such operations performed by im at the Leicester school clinic during a period f ten years. In the first place, as he points out, he various sequelæ cannot, of course. always be onnected directly with the operation. Tonsillecomy is performed throughout the year, irrespective f season or weather ; many of the children come rom, and quickly return to, overcrowded homes, nd have attended school on the day before peration, where they are subject to infection with olds and with the infectious fevers. On the whole, herefore, it is surprising that more children do ot have some disturbance of convalescence, and perations must occasionally be performed on those who are sickening for some infectious illness. This point is well brought out by Mr. Keen's figures of the incidence of the acute specific fevers after the tonsil and adenoid operation which are as follows : diphtheria 3, measles 4, mumps 2, whooping-cough 1, and chicken-pox 7, with 5 doubtful cases of scarlet fever, and 18 cases of scarlatiniform rash. All three cases of diphtheria were of a severe laryngeal form, and two of the patients died. In these, as in other types of infectious fever, there is probably no direct relationship between the disease and the operation, but scarlet fever stands in a different category. A difficulty here is that we may have to deal with the so-called "surgical scarlet fever," which is perhaps not true scarlet fever at all. In Mr. Keen's series 18 patients developed a fleeting scarlatiniform rash, usually with a slight rise of temperature. on the second or third day. and he believes that such rashes are not very uncommon after this operation, for they are easily overlooked in the absence of a routine follow-up of cases In addition, five of his patients were sent to the isolation hospital by their own doctors with the diagnosis of scarlet fever : he analyses these cases and comes to the conclusion that they were not true scarlatina but surgical scarlet fever, appearing on the second or third day after operation, of a mild type, and not infectious to others. He believes that this condition is due to infection by some other strain of the streptococcus group but not by that of true scarlet fever. It is noteworthy that the healing of the wounds in the throat is not delayed.

It is otherwise with post-operative septic complications, which in a mild form are not uncommon : here the inflammation does not remain superficial and strictly localised, but spreads to the soft palate or pharynx with delayed healing and more or less severe toxæmia, and later with excessive formation of scar tissue. Mr. Keen estimates that at least one child in every 20 or 30 has some delay of convalescence of this nature. Generalised sepsis, or septicæmia, is fortunately rare, but he encountered five cases in this series with one death ; inflammation of the ears or lungs may occur as complications, but the main disease is a generalised infection. Cervical adenitis is not very unusual ; when glands were enlarged before. they often become larger after operation. though this is quite temporary ; but acute swelling of glands not previously enlarged may also occur, accompanied by a sharp rise of temperature. There were five cases of this kind in the series, and all subsided without suppuration. Of pulmonary complications, all, amounting to 23, were instances of lobar pneumonia, bronchopneumonia, and acute bronchitis. The throats showed no exceptional sepsis and healed in a normal way. A fact of interest is that the seasonal incidence was the same for the summer as for the winter months, but the children are kept in the clinic for 24 hours after operation. Mr. Keen thinks that the development of these acute pulmonary infections may be explained by the possibility that the operation is performed during the prodromal stage of an infection. He rules out irritation of the bronchial mucous membrane by the anæsthetic on the ground of the short administration, which averaged under four minutes, and he considers that this complication cannot be caused by inhalation of blood or septic material, because the operation is a very quick one with the guillotine, the head is kept in the extended position during the manipulations, and the child is turned on to the side immediately afterwards. It will probably not be universally agreed that even these factors are sufficient to prevent altogether the aspiration of material from the throat during operation; the experiments of MAY, THOBURN, and ROSENBERGER,[2] by radiography after the instillation of iodised oil, seem to show that some degree of aspiration is the rule, but that elimination is very rapid. Aspiration is a probable cause of pulmonary abscess, but of this there was no case in the series, and Mr. KEEN's suggestion is a likely one that an infection, already present, was aggravated by the trauma of operation.

---

[1] Jour Laryng and Otol , January, 1932, p 1.

Acute suppurative otitis is an important complication, of which there were 60 cases in this series of 9344 operations, besides seven cases of recurrence of a previous otorrhœa. Among these 60 patients were six extremely serious cases of mastoid and intracranial complications with three deaths. These figures are in accordance with the general opinion that acute suppurative otitis is exceptionally virulent when it occurs as a complication of the tonsil and adenoid operation. As referred pain in the ear is frequent, and must be distinguished from true otitis, Mr. KEEN wisely writes of the advisability of removing cerumen before the operation, and he also mentions the harmful effect of letting cold water get into the ear while sponging the face after operation. In his series the infection occurred in the right ear in 37 cases, and in the left in 15, and he found that nearly twice as many children lay on their right side than on their left, thus facilitating the infection of the right Eustachian tube. Incidentally this finding points against damage by cold water, for patients are usually turned on to the right side after the operation. Mr. KEEN also encountered five cases of glottic spasm, three on the operating table and two in bed but before coming round from the anæsthetic; they appear to have been severe, for laryngotomy was performed in one, and on two of the others an incision was begun before the glottis relaxed. This does not agree with the contention that no blood can be aspirated during the operation, for the spasm is almost certainly cause by its entry into the larynx. There was also very unusual case of subcutaneous emphysema apparently caused by glottic spasm and alveola rupture, on the day following operation.

ANNOTATIONS

THE COST OF ENGLISH MORALS.

To the lay observer the outlook of the medical profession sometimes exhibits a puzzling mixture of realism and conventionalism, of originality and orthodoxy, of courage and of timidity. This mystifying compound is noticeable in some specialities more than in others. In the specialty of venereology, the outlook is predominantly realistic; here the principles of treatment are adjusted to situations which exist rather than to those which ought to exist. With regard to the principles of prophylaxis, however, medical opinion is—or at any rate was only a short time ago—less unanimous, and was undoubtedly influenced by the different expressions of lay morality. In psychiatry, there prevails a distinctive outlook in such matters as criminal responsibility and the sexual perversions. In relation to certain topics of obvious medical significance, the main body of medical thought is held by some to follow timidly behind an advance guard of lay opinion. There has probably never been an age in which current ideas on sexual questions have been more heterogeneous, fluctuating, and uncertain than the present. The problems of divorce, of regulation of parenthood, of sex education, of preparation for marriage, all of which, in the wider sense, have medical significance, are freely discussed in the press and in popular lectures. Yet medical opinion upon them remains uncrystallised if not actually chaotic. "In regard to these things," writes Sir Thomas Horder in a cautious yet appreciative introduction to a book dealing with these subjects, "there is in England a tremendous and not uncharacteristic inertia." The book, entitled "The Cost of British Morals,"[1] is a forcible and eloquent expression of "advanced" lay opinion. Mrs. Chance's central theme is that the veil of silence which, during the last century, enshrouded all that pertained to human reproduction—a silence which the scientific spirit is now only beginning to penetrate—has cost us much avoidable suffering. In successive chapters she gives illustrations of the
timidity both of the medical and lay approach to t
problems of sexual physiology, sexual educatio
birth control and abortion, and she points to t
sacrifice of happiness which this attitude carries
its train. The book is an energetic and convinci
plea for enlightened investigation, which should p
voke discussion and will be read with profit by man

PERIPHERAL VASCULAR DISEASE.

Now that many peripheral lesions, the result
vascular occlusion, may be relieved by surgery
the sympathetic nervous system, it is becomi
increasingly important that those lesions due
vasomotor spasm should be easily and clea
differentiated from those in which the underlyi
pathological condition is an obliterative disease of
artery and it is useless to hope for improveme
from operation. W. J. M. Scott and J. J. Morto
find that it is possible to gauge the part played
sympathetic vaso-constriction, and thus foretell
probable results of sympathectomy, by means
anæsthesia. They show that under deep gene
anæsthesia or under spinal anæsthesia the sympathe
fibres are paralysed and a uniform degree of va
dilatation is produced all over the area anæsthetis
—that is, of course, assuming that the vascu
supply of the area is intact. As a result of this va
dilatation the skin temperature rises in nor
subjects, at room temperature of 20° C., to at le
31·5° C. (88·7° F.). If the vessel supplying the par
occluded by a structural defect there is vaso-dilatat
and no rise in skin temperature, while if the obstruct
is partly spastic and partly organic the temperat
rises but does not reach the normal level. Clos
similar results are obtained by using a local an
thetic to block the peripheral nerves supplying
part, but the rise in temperature is about 1° C. bel
that reached with spinal or general anæsthesia, si
those sympathetic fibres reaching the vessel hig

) the limb are left unanæsthetised. By this method ott and Morton find it easy to assess the degree to hich the vascular obstruction will be relieved by mpathectomy and thus to choose their cases r operation with more success. P. G. Flothow[2] is obtained similar results, but he prefers to inject e sympathetic ganglia supplying the affected part ith a local anæsthetic. By this method he claims at not only are all the sympathetic fibres eliminated it that also the degree to which pain will be relieved r operation may be prejudged. It is stated that e technique of these injections is simple and that ey cause little discomfort.

REGENERATION OF THE UTERINE MUCOSA AFTER DELIVERY.

The involution of the puerperal uterus is one of e most remarkable processes met with in the dy. It leads in the short space of six weeks to the duction in size of the uterus from that of an dominal tumour extending nearly to the level of e umbilicus at the end of the third stage of labour dimensions which differ very little from those of e virgin uterus. The process is of necessity complex d much of it is but little understood. Histological vestigations are handicapped by scarcity of material, r it is only rarely that uninfected specimens are tained. The involution of the muscle-fibres nsists of a granular atrophy without fatty degenera-on and there is no evidence that individual fibres e absorbed. The involution of the vessels is ifficult to interpret, and at the present time the ntradictory views of Goodall[3] and Wilfred Shaw[4] e disputed. More is known of the regeneration of e mucous membrane of the uterus, for Teacher's[5] ntribution in 1927 cleared up some of the difficulties. he late Prof. Whitridge Williams[6] shortly before his eath called attention to the involution of the lacental site and based his views upon the study of ghteen uninfected puerperal uteri. It is well known at the placental site is sometimes difficult to lentify immediately after delivery, but within a w hours, probably owing to the relaxation of the terus, its sinuses become engorged with blood. he sinuses become thrombosed and are then readily ecognised by their vascularity; moreover the lacental site projects above the general surface of he lining membrane of the uterus. Involution of he placental site proceeds until by the end of the ixth week after delivery the endometrium lines the nucous membrane of the uterus completely, and nacroscopical examination reveals little trace of the ituation of the placental site. The mechanism of he renovation of the rest of the endometrium is elatively simple. The line of cleavage between the nembranes and the uterus is through the spongy ayer of the decidua, and after expulsion of the placenta nd membranes a raw area remains which oozes lood and serum. The superficial part of this zone ecomes infiltrated with leucocytes, and by necrosis he remnants of the spongy layer are shed to form art of the lochial discharge. The cells of the basal ayer of the glands then grow over the denuded rea in a way which is comparable to the process f repair after menstruation. The most striking eature of the renovation is its rapidity, and Whitridge Williams was able to confirm the accepted view that involution of this part of the endometrium is completed by the third week of the puerperium. The involution of the placental site zone is, as might be expected, much more intricate, and six weeks elapse before the placental site is covered by endometrium. Whitridge Williams showed that leucocytic infiltration and necrosis can be demonstrated in the superficial layers in the first two weeks of the puerperium, and that this zone is shed in a way similar to that obtaining over the rest of the endometrium. The thrombosed sinuses and vessels develop hyaline tissue in their walls and are reduced in size partly by subendothelial proliferation and partly by absorption of the hyaline tissue. The main point of Whitridge Williams's thesis is that the bulk of the placental site is actually exfoliated during the fourth and fifth weeks of the puerperium. Exfoliation is produced as a result of the activity of the adjacent endometrium which undermines the placental site and detaches it from the wall of the uterus. This mechanism is assisted by the hypertrophy *of the fragments of the basal layer of the* endometrium which lie between the placental site and the wall of the uterus. The evidence which is brought forward is fairly convincing, and the only difficulty in accepting the explanation is that there is not a characteristic uterine discharge at this phase of the puerperium. It is interesting to notice that the only previous observations on the puerperal uterus which suggest a similar mechanism are those of Ries which were published some forty years ago. The histology of the involution of the puerperal uterus is worth further study.

CARDIOLOGICAL DIAGNOSIS.

Two useful pamphlets[1] have recently been published by the heart committee of the New York Tuberculosis and Health Association. They deal with the criteria for the interpretation of electrocardiograms, and with radiological diagnosis in heart disease. One of the principal objects of the Association is to achieve a standard nomenclature and thereby render comparable the results obtained by different workers. Such uniformity would also facilitate the study of cardiological problems from the statistical aspect. In the pamphlet dealing with electrocardiography 50 variations in the form of the record are described. Of these, 27 are concerned with the heart's rhythm, three with deviation of the electrical axis, and the remainder with the form of the different deflexions which constitute the auricular and ventricular complexes. The list of phenomena considered includes all the common deviations from the normal, and the only feature which might, perhaps, be regarded as an unnecessary refinement is the subdivision of the duration of the Q R S complex into three (short, medium, and long) instead of the usual two types (less than and greater than 0·1 sec.). The pamphlet is illustrated by a series of typical records. The pamphlet on Radiologic Diagnosis in Heart Disease opens with a simple and lucid account of the methods of procedure. It then deals with the diagnosis of enlargement of the various cardiac chambers and of the aorta, stress being laid on the fact that it is much more important to ascertain which chambers of the heart are involved rather than to obtain an exact measurement of the size of the whole heart. In place of actual radiograms a series of 31 line diagrams are given. These serve to illustrate clearly the various features described in the text. In the preface Dr. Alfred E. Cohn points out that this is merely a tentative effort at classification, and necessarily incomplete; but that the authors are to be congratulated on producing such a helpful introduction to a difficult subject.

THE TREATMENT OF PRURITUS SENILIS.

THE ætiology of pruritus senilis is frequently obscure. It is not an uncommon symptom, and is one of the most lamentable and intractable of the penalties of old age. The hypothesis of essential skin changes of a degenerative type, with loss of elastic fibres, is no longer tenable, for the large majority of individuals with senile atrophic skin do not have pruritis. It is essential in every case to exclude such obvious causes as pediculi, cystitis with an enlarged prostate, strictures, and latent carcinoma, especially of the liver. Dr. H. Abelson,[1] of Leipzig, believes he has established another factor in a metabolic undernourishment of the cutis due to senile changes in its circulation—i.e., a cutaneous arterio-sclerosis. For many years he has always given iodine to such patients with benefit, and for the last six months has obtained encouraging results with a skeletal muscle extract—lacarnol. This drug—the main indication for which is angina—is quite harmless, and is prescribed in drop doses on sugar, up to 12 or 15 drops t.d.s. In eight of Abelson's cases there was so much improvement in a week that the patients are stated to have forgotten to apply local antipruritics. Further benefit was obtained by 1 c.cm. injections hypodermically twice a week. This group of cases and three more were completely cured of itching in four weeks, but in a third group of 12 cases this happy result was not secured, and the patients had to continue to seek relief by local measures after a six weeks' trial of lacarnol. The element of suggestion cannot easily be excluded, especially in such a small series of cases, but the good results in nearly half the cases suggest a trial of this method.

PRIMARY CARCINOMA OF THE LUNG.

THE recent increase in the number of cases of primary carcinoma of the lung may not be real, but certainly more cases are being reported. Dr. B. M. Fried, in a clinical and pathological study,[2] states his opinion that the increase is due to more accurate diagnosis, the fact that attention has been focused on the condition, and an increase in the span of human life. Though this is a comforting suggestion, autopsy reports from the large hospitals cannot be ignored. James Maxwell from London, J. B. Duguid from Manchester, W. Kikuth from Germany, and C. V. Weller from America, and other workers report a definite and steady increase in the percentage of carcinomata of the lung seen at autopsies, and also an increased proportion in relation to the total number of malignant growths. Maxwell notes that "the thorax is assuming increasing importance as a primary site of malignant disease." Dr. Fried reviews again the possible ætiological factors that have been blamed, such as influenza, tarred roads, tuberculosis, syphilis, and trauma, but has to reject each in turn. If more space in the literature on bronchial carcinoma were given to diagnosis, especially early diagnosis, and less on histogenesis and metastases, the average medical reader would be grateful. Dr. Fried is not very helpful in this respect, but he does add one new idea of importance. He suggests that bronchial carcinoma frequently runs a protracted course, often of several years' duration, during which time the patient's symptoms suggest only a mild inflammatory disease of the bronchi. In Dr. Fried's view, practitioners are so obsessed with the terminal picture of this disease as seen in the post-mortem room that they are inclined to forget the onset: that two years before their patient started having bronchitis and that his sputum was occasionally streaked with blood. The difficulty facing the practitioner is that if he is to make an early diagnosis he must subject the patient to special examination, such as bronchoscopy and X rays, at a time when the complaint is only of what may appear trivial pulmonary symptoms. To wait nowadays for physical signs to develop before making a diagnosis of pulmonary tuberculosis is to deny to the patient the best chance of recovery; and this is true, also, of pulmonary cancer.

Directly opposed to the theories of Dr. Fried are those of Dr. Jacob Polevski.[3] He maintains that primary cancer of the lung can be diagnosed clinically by the characteristic history and physical signs, that fluoroscopy is of great aid in doubtful cases, but that bronchoscopy and biopsy are rarely necessary. This expectant attitude can hardly be justified, since progress cannot be anticipated unless active steps are taken to ensure early diagnosis. Dr. Polevski reports nine cases, all of which showed on the X ray a shadow extending out to the periphery of the lung. This is, unfortunately, the stage at the time many patients seek advice, but the absence of such pronounced signs by no means excludes cancer. Primary cancer of the lung originates in the bronchial mucosa near or around the hilum of the lung. X rays will not show any abnormal shadow until the growth has spread into the surrounding tissue, or, what is more frequent, has grown into and obstructed the lumen of the bronchus, causing atelectasis and pneumonitis in the obstructed area of the lung. It is only with the bronchoscope that we can hope to see the beginnings of this disease. Chevalier Jackson has so popularised bronchoscopy in the United States that the practitioner does not hesitate to recommend it to his patient any more than he would hesitate to advise cystoscopy in an obscure case of hæmaturia. More bronchoscopic clinics are needed in England, though it must be confessed that even with an early diagnosis the outlook is still gloomy. X ray therapy can offer only palliative treatment, while radium and partial pneumectomy are still in the experimental stage. The results of these are sufficiently encouraging to offer at least a slight hope for the future.

HEALTH OF THE ARMY IN 1930.

THE report[4] on the health of the Army in 1930, signed by Lt.-Gen. Sir H. B. Fawcus, Director-General, Army Medical Services, registers further advances in the struggle for scientific recognition, treatment, and prevention of disease in the Army. The report is concerned with 10,972 officers and 178,384 other ranks. The figures of illness which it records are nearly all lower this year, probably because there was no considerable outbreak of influenza in 1930. The admissions to hospital per thousand were 428·4 (468·5 in 1929), deaths 2·32 (2·45), finally invalided 9·28 (10·1), and constantly sick

[2] Medicine, 1931, x., 373.

[3] Arch. Intern. Med., 1931, xlviii., 1126.

[4] H.M. Stationery Office. 1932. pp. 151. 2s. 6d.

4·1 (26·12); the numbers of out-patients were also ss. 2524·9 daily (2742·6). Among the chief causes r admission to hospitals were digestive diseases her than those of liver and tonsils 55·1 (55·4) er thousand. injuries 52·8 (52·1), malaria 41·3 (41·2), flammation of areolar tissue 34·5 (34·7). venereal seases 34·5 (35·0). The admissions for dysentery, nd-fly fever, and scabies showed a slight increase; r influenza, enteric fever, pulmonary tuberculosis, nd pneumonia there was a slight decrease. he final invaliding rate was 9·28 (10·1). The chief ss of service is through gonorrhœa. The death-te of women is raised, apparently by increase in eaths from diseases of the generative system. other and child welfare committees are formed in ll large stations and are credited with excellent work. he slight increase in dysentery is thought to be ue to better diagnosis of cases formerly returned as olitis or diarrhœa. In India some 80 per cent. of ses of dysentery are bacillary. but in Shanghai mœbic are the more numerous. Some epidemics of nteric fever are thought due to ambulant, nrecognised cases, perhaps styled "P.U.O." The revention of malaria in Shanghai has been difficult. he huts are on Chinese ground, surrounded by nals; the municipality oiled these. but the smell f the oil caused complaints from the neighbours. usting with Paris green was the method then tried, ut the neighbours' ducks ate that and died. Insect-ating fish were next procured, in the hope that they ould eat the larvæ. but this was a vain hope, for the ucks and their owners made joint onslaughts on the sh. Meantime malaria in the force at Shanghai as trebled. It looks as if the huts there will have o be mosquito-proofed. Screening of barracks roceeds in India. but only slowly. Plasmoquine s being tried and is giving satisfaction; in one roup of 233 cases there were only five relapses. he case-mortality of pneumonia is the same as it as forty years ago (10 per cent.). There is much ess invaliding for middle-ear diseases since electrically ighted otoscopes have been supplied to recruiting nedical officers. There were removed from knee-joints 38 internal. 28 external semilunar cartilages. and ll the patients returned to duty. Two cases of ysticercosis are reported, and several of oriental ore occurred at Quetta. The care with which the hysical training of the recruit is conducted deserves very praise. To test the effect of tobacco-smoking n endurance. a three-mile run was held among 1885 men in 19 races; of the non-smokers 18·7 per cent. got into the first ten places, of the moderate smokers 8·4. of the heavy smokers only 6·2. It is said that practically all recruits are total abstainers. Tuber-culosis continues to cause permanent loss to the service. 231 cases, with 31 deaths, 200 finally invalided, the percentage increasing with age and service. Bacteriological examinations are proving more and more effective as aids in diagnosis and treatment in the Army, and this fact provides one of the most encouraging features of this interesting report.

PATHOLOGY OF ENDOTHECAL INJECTION.

LITTLE is known of pathological changes which may be caused in the spinal cord by injections for spinal analgesia. It is true that now and then reports appear of neurological symptoms attributed to endothecal injections, but these are extremely rare, and actual post-mortem evidence of spinal cord damage is rarer still. Experimental proof of changes brought about in the nervous tissue of the cord when endothecal injections were made in dogs is now provided.[1] The authors describe and figure changes in the ganglion cells of the grey matter of the cord similar to those seen in Wallerian degeneration, swelling and fragmentation of axis cylinders. and signs of degenerative changes in the tracts of the cord. The dogs were killed at various periods, and after injections of various strength. The investigators point out that the last of these changes were not pronounced in cords of animals allowed to live for 90 days. It is possible that all the changes described were transitory. We anticipate with interest the fulfilment of the authors' hope that their studies may be extended to the cords of human beings. and the results incorporated "with those clinical observations which have been made in careful neurologic examination of patients operated on under spinal analgesia."

THE DECLINE IN THE MORTALITY FROM TUBERCULOSIS.

THE mortality from tuberculosis has been declining steadily in this country since 1866, with one notably exceptional period during the war years. As the Registrar-General's annual reports show, the standardised death-rate from all forms of tubercle for the decennium 1851–60 was 3478, while in 1929 it was 932 per million of the population. The corresponding figures for the pulmonary form of disease were 2772 and 738. The fall in the death-rate from non-pulmonary tuberculosis has not been so continuous as that observed for the pulmonary form. lagging till 1891 and then dropping with remarkable acceleration during the succeeding twenty years. So far as existing records reveal the true state of affairs. there appears to have been no decline in the curve between 1855 (when registration commenced) and 1866. Judging from the available information it may be conjectured that there was probably a rise in mortality from tuberculosis in the first half of the nineteenth century. concurrently with the increase in the general mortality-rate which seems to have occurred during that period.

At a meeting held on Jan. 15th the Society of Medical Officers of Health discussed the causes of these phenomena. The subject was introduced by two officers engaged in the tuberculosis service. Dr. Lissant Cox in Lancashire and Dr. E. Ward in Devonshire, their respective areas differing considerably in character and population. There was little difference of opinion on the broader aspects of the question either between them, or among most of the subsequent speakers. It seemed to be generally accepted that the raising of the standard of living, with consequent improvement of nutrition, was a prime cause of the decline of tubercle, and that reduction of overcrowding in houses, better sanitation, improved habits of cleanliness of the people as the result of better education. better working conditions, and improvement of the milk-supply were among the reasons for the fall in mortality before specific schemes for the prevention and cure of tuberculosis came into action. It was not forgotten that segregation of the advanced case, and therefore the limitation of mass infection, came into play long before the National Insurance Act of 1911, and the Tuberculosis Regulations of 1912 inaugurated the tuberculosis schemes of county and county borough councils; the steadily increasing hospital accommodation of the guardians was being extensively utilised for this purpose. Hardly a doubt was raised about the value of the now well-established schemes of early diagnosis, surveillance of contacts, specific forms of treatment in and outside of sanatoriums, hospitalisation of the advanced cases, and education of patients in methods of preventing the spread of infection. There is, indeed, some evidence that the death-rate has fallen more rapidly in recent years in those towns which have made the most extensive institutional provision. The continued application and perfection of these measures is a commitment of modern civilisation, but their actual share in the cause of the decline of mortality of tuberculosis is difficult to detect, as Prof. E. L. Collis pointed out. Indeed, there were murmurs of assent when Sir StClair Thomson asked whether tuberculosis might not be dying out of its own accord. This is perhaps really a suggestion that sudden migrations and increases of population such as occurred one hundred years ago, followed by relative stabilisation of town and country stocks and a falling birth-rate, may have had more to do with the rise and fall of tubercle than the less definitely social considerations which bulk large in the medical mind. It is at least gratifying to observe that the decline has continued with hardly any arrest of the rate of acceleration (except in the case of pulmonary tuberculosis in females aged 15–20 years) during the past ten years of increasing financial embarrassment.

BRILLIANT GREEN FOR SYCOSIS.

A SIMPLE and cheap method of treating sycosis has recently been described by Prof. Senin (Nijni-Novgorod)[1] which, if the results recorded are confirmed, will revolutionise the treatment of one of the most intractable of all dermatoses. All crusts and scales are first removed by maceration with a 5 per cent. salicylic ointment. Epilation of loose pustule-encircled hairs should follow, and then the affected areas are conscientiously painted every day or every other day with a 1 per cent. alcoholic solution of brilliant green in 70 per cent. alcohol; 53 cases were cured after 12–25 applications of the solution. There were no relapses after a year, and a fair proportion had been treated previously without much result by X rays, vaccines, and other accepted procedures. Such results transcend the most optimistic of any yet reported, and as brilliant green has no toxic properties it will doubtless receive universal trial, in spite of the temporary inconvenience occasioned by its colour. In this country it has often been recommended for ulcers of the leg, and in ecthymatous conditions generally, and its bactericidal qualities have recently been tested by Dr. L. P. Garrod.[2] He found, from in vitro experiments, that the bactericidal action of brilliant green compares very favourably with that of most antiseptics, with the notable exception of iodine; and that its bactericidal action in the presence of 5 per cent. of blood greatly exceeds that of iodine. The conclusion he draws is that the value of iodine as a sterilising agent for a bleeding surface is overrated, and he goes so far as to suggest that it should be replaced for routine prophylactic use in the first treatment of wounds by the emulsion forming coal-tar germicides. Dr. Garrod believes that the proper treatment of a skin injury which is likely to be infected (such as a cut, scratch, or puncture accidentally inflicted during a septic dressing, operation, or autopsy) is the application either of acriflavine or rivanol, or of one of the highly germicidal dyes, such as crystal violet or brilliant green. In the case of punctured wounds (pinpricks or stabs by a scalpel point) he recommends the injection of the germicide with a syringe. He states that the combination of these two dyes known as "blue paint," which was recommended for obstetric and gynæcological use by Mr. Victor Bonney and Prof. C. H. Browning as long ago as 1918, has a bactericidal action in short periods greatly exceeding that of any other agent tested.

CANCER IN AMERICAN EX-SERVICE MEN.

Dr. Philip B. Matz, in the United States, has made a study of cancer in veterans from the world war, the Spanish-American war, and various expeditions.[1] He finds that only 16·3 per cent. of those affected gave a hereditary or familial history, but the smallness of this proportion, he thinks, may be due to the fact that most of the ex-Service men have not yet reached "the cancer age." The most frequent sites of disease were the skin, lip, stomach, lymphatic glands, rectum, buccal cavity, and bladder. The most frequent histological types were adenocarcinoma, basal cell carcinoma, and squamous cell carcinoma. The mean age of the whole group at the time of onset was 45 for carcinoma and 36 for sarcoma, the youngest being 20 and the oldest 91. No correlation was found between weight and development of cancer. Of 48 cases of cancer of skin or mucous membrane, 25 were farmers or ranchers, exposed to actinic rays and the rigours of an outdoor life. In the whole group, 40 per cent. gave a history of previous irritations or chronic inflammatory process and 27·6 per cent. had had a pre-cancerous condition of some kind. The early symptoms were usually swelling, pain, ulceration, bleeding, or loss of weight, but pain was such an unimportant factor that many patients did not seek advice in the early stages. There was again a delay in diagnosis when they did seek medical aid, with the result that on an average they were treated for 29·7 months before they were diagnosed. Among 89 ex-Service men who died, the duration of illness varied from two months to 156 months, the average being 25·6 months. The average for carcinoma was 28·3 months and for sarcoma 18·2 months. These figures form an interesting contrast with those recently published by the Ministry of Health.[2] The London cases passed very rapidly from the first symptom noticed to efficient diagnosis, and the disease took a much more rapid course. The patients were on the whole, however, much older people.

INDEX TO "THE LANCET," VOL. II., 1931.

THE Index and Title-page to Vol. II., 1931, which was completed with the issue of Dec. 26th, is now in preparation. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of the fever hospital medical service group of this society will be held at 1, Upper Montague-street, London, W.C., at 4 P.M., on Friday, Jan. 29th, when Dr. F. W. Goodall will deliver a presidential address on Pre-bacterial Views of Infectious Diseases.—The maternity and child welfare group will hold a joint meeting with the Pagans, a group of pædiatricians, at the same address, at 8.30 P.M., on the same day. There will be a discussion on Future Policy with regard to Medical Staff Appointments in Child Welfare Clinics.

SPECIAL ARTICLES

MEDICINE AND THE LAW.

Alleged Personation of a Doctor.

George Edward Williams, the medical attendant ho has been charged at Marlborough-street police-urt with offences against the Dangerous Drugs *onsolidated) Regulations*, was on Jan. 15th com-itted for trial at the Central Criminal Court. As dicated in a note on the case in our columns last ek, further charges of a serious nature have now en outlined. It was alleged that he had falsely orn that he was a registered medical practitioner hen giving evidence at Clerkenwell county court st August. The managing clerk to a firm of solicitors ated that he had known Williams for about a year, d that Williams gave medical evidence in the unty court in connexion with a case of suggested od poisoning; Williams had given his evidence the name of George Edward Williams, with the ualifications M.D. Camb., M.R.C.S., L.R.C.P., D.P.H., d had claimed to have been practising as a doctor r 26 years. A clerk from the office of the General edical Council said that the Dr. George Edward illiams whose name and address was in the register as Dr. George Edward Williams, of Rhostryfan, arnarvonshire. The son of Dr. Williams, of hostryfan, said that his father, who practised in arnarvonshire, was ill and unable to attend the urt; the witness did not know the accused.

A further charge related to the making of a false atement for the purpose of obtaining a passport st September. A clergyman of Upper Marylebone-reet said he had certified an application for a ssport on behalf of the accused, who had described mself as a physician and surgeon, and had declared at there had been no change in his name. A tective-inspector stated that the accused had said him: "I have been known as Williams for five ears; as you know, my name is Flaxman."

The accused has reserved his defence, and bail as been allowed.

A Guaranteed Cure.

Advertisers who, to put money in their pockets, fer extravagant and ridiculous guarantees in respect their goods, cannot complain if a customer occa-onally takes them at their word. This happened the recent case of Wood *v.* Lektrik, Ltd., which, Mr. Justice Rowlatt's judgment is challenged in e Court of Appeal, is sure to find a place in the gal text-books as an illustration of various points the law of contract. The defendant company dvertised "New hair in 72 hours. Lektrik Electric omb. Great news for hair sufferers. What is *your* ouble? Is it grey hair? In ten days not a grey air left. £500 guarantee." Mr. Wood, the plaintiff, ought one of the advertised combs and followed the irections ("to get the full benefit you should use it r five minutes"). He used the comb night and orning and occasionally during the day at his fice as well, but the guaranteed cure of his greyness roved a failure. He sued for his £500 and won his ase, subject to a possible appeal. Some of the efendant company's points seem commercially rather ynical. Their first contention, that the so-called uarantee was a mere flourish, was rejected; the udge took it to be a serious statement. The second ontention was an attempt to throw over their own dvertisement as something framed by an advertising agency and not authorised by themselves. This slender defence was rejected also; they had paid the agency's bill and had never repudiated the advertisement, but had accepted the profit of whatever sales accrued therefrom. Thirdly, it was suggested that the guarantee of £500 merely guaranteed the repayment of the price of the comb (3*s.* 6*d.*) if the customer wanted his money back. It appeared that in other instances the advertisements had contained a coupon explaining this remarkable limitation; but, as there was no such coupon in the announcement which attracted Mr. Brown, the suggested limitation was inoperative. Next the defendants said there *could be no valid legal contract if there was impossibility of performance.* With unusual candour they adopted the position that their comb could really never do what the advertisement promised on its behalf. They correctly argued that no legal consequences arise if someone promises the impossible; but unfortunately the advertisement expressly precluded the idea of impossibility. The combs, it said, were used by all grades of society, including Royalty; "*not one has failed to do everything we claim for it.*" Moreover, the advertisement contained a picture of a man living at Forest Hill with his statement that his hair was very thin and going grey, but on the tenth day the greyness had gone entirely; "that Lektrik comb of yours has done the trick." Lastly, the defendants alleged that the plaintiff had not used the comb properly and that anyhow he had not proved that he had not got fresh hair growing from the roots. The judge was unimpressed by these arguments also. He held that the comb had failed in its operation and that the plaintiff, having complied with the advertisement, had made a valid contract and was entitled to the guarantee of £500.

Mr. Justice Rowlatt is known as a judge who decides upon first principles, and is but little swayed by the citation of leading cases. There is, as it happens, a leading case on the law of contract—Carlill *v.* Carbolic Smoke Ball Company—which is closely parallel. Some 40 years ago, when influenza was a greater novelty, a firm advertised the merits of its carbolic smoke ball, and offered £100 to anyone "who contracts the increasing epidemic influenza colds, or any disease caused by taking cold, after having used the ball three times daily for two weeks according to the printed directions." Mrs. Carlill used the smoke ball for several weeks, but contracted influenza. She sued for her £100 and won. The defendants said there was no contract because the firm had not been notified of the acceptance of its offer. The court held that the case resembled that of a reward offered for the recovery of lost property—anyone who performed the condition must be taken to have accepted the offer without further ado. As in the comb case, the defendants said the advertisement was a mere puff which no reasonable person would take seriously. But the advertisement had announced that the firm had deposited £1000 with the Alliance Bank to "show our sincerity in the matter." The plaintiff's victory in the carbolic smoke ball case was upheld by a strong Court of Appeal. Lord Justice Bowen agreed that ordinarily the acceptance of an offer must be notified to the offerer, in order that the two minds may come together and a valid contract be formed. But a person who makes an offer can expressly or impliedly intimate that a particular mode of acceptance will suffice to make the bargain binding. If so, it is only well-established schemes of early diagnosis, surveillance of contacts, specific forms of treatment in and outside of sanatoriums. hospitalisation of the advanced cases, and education of patients in methods of preventing the spread of infection. There is, indeed, some evidence that the death-rate has fallen more rapidly in recent years in those towns which have made the most extensive institutional provision. The continued application and perfection of these measures is a commitment of modern civilisation. but their actual share in the cause of the decline of mortality of tuberculosis is difficult to detect, as Prof. E. L. Collis pointed out. Indeed, there were murmurs of assent when Sir StClair Thomson asked whether tuberculosis might not be dying out of its own accord. This is perhaps really a suggestion that sudden migrations and increases of population such as occurred one hundred years ago, followed by relative stabilisation of town and country stocks and a falling birth-rate, may have had more to do with the rise and fall of tubercle than the less definitely social considerations which bulk large in the medical mind. It is at least gratifying to observe that the decline has continued with hardly any arrest of the rate of acceleration (except in the case of pulmonary tuberculosis in females aged 15–20 years) during the past ten years of increasing financial embarrassment.

BRILLIANT GREEN FOR SYCOSIS.

A SIMPLE and cheap method of treating sycosis has recently been described by Prof. Senin (Nijni-Novgorod)[1] which, if the results recorded are confirmed, will revolutionise the treatment of one of the most intractable of all dermatoses. All crusts and scales are first removed by maceration with a 5 per cent. salicylic ointment. Epilation of loose pustule-encircled hairs should follow, and then the affected areas are conscientiously painted every day or every other day with a 1 per cent. alcoholic solution of brilliant green in 70 per cent. alcohol; 53 cases were cured after 12–25 applications of the solution. There were no relapses after a year, and a fair proportion had been treated previously without much result by X rays, vaccines, and other accepted procedures. Such results transcend the most optimistic of any yet reported, and as brilliant green has no toxic properties it will doubtless receive universal trial, in spite of the temporary inconvenience occasioned by its colour. In this country it has often been recommended for ulcers of the leg, and in ecthymatous conditions generally, and its bactericidal qualities have recently been tested by Dr. L. P. Garrod.[2] He found, from in vitro experiments, that the bactericidal action of brilliant green compares very favourably with that of most antiseptics, with the notable exception of iodine; and that its bactericidal action in the presence of 5 per cent. of blood greatly exceeds that of iodine. The conclusion he draws is that the value of iodine as a sterilising agent for a bleeding surface is overrated, and he goes so far as to suggest that it should be replaced for routine prophylactic use in the first treatment of wounds by the emulsion forming coal-tar germicides. Dr. Garrod believes that the proper treatment of a skin injury which is likely to be infected (such as a cut, scratch, or puncture accidentally inflicted during a septic dressing, operation, or autopsy) is the application either of acriflavine or rivanol, or of one of the highly germicidal dyes, such as crystal violet or brilliant green. In the case of punctured wounds (pinpricks or stabs by a scalpel point) he recommends the injection of the germicide with a syringe. He states that the combination of these two dyes known as "blue paint," which was recommended for obstetric and gynæcological use by Mr. Victor Bonney and Prof. C. H. Browning as long ago as 1918, has a bactericidal action in short periods greatly exceeding that of any other agent tested.

MEDICINE AND THE LAW.

Alleged Personation of a Doctor.

George Edward Williams, the medical attendant who has been charged at Marlborough-street police-ourt with offences against the Dangerous Drugs Consolidated) Regulations, was on Jan. 15th committed for trial at the Central Criminal Court. As ndicated in a note on the case in our columns last week, further charges of a serious nature have now been outlined. It was alleged that he had falsely worn that he was a registered medical practitioner when giving evidence at Clerkenwell county court ast August. The managing clerk to a firm of solicitors tated that he had known Williams for about a year. nd that Williams gave medical evidence in the ounty court in connexion with a case of suggested ood poisoning; Williams had given his evidence n the name of George Edward Williams, with the qualifications M.D. Camb., M.R.C.S., L.R.C.P., D.P.H., and had claimed to have been practising as a doctor or 26 years. A clerk from the office of the General Medical Council said that the Dr. George Edward Williams whose name and address was in the register was Dr. George Edward Williams, of Rhostryfan, Carnarvonshire. The son of Dr. Williams. of Rhostryfan, said that his father, who practised in Carnarvonshire, was ill and unable to attend the ourt; the witness did not know the accused.

A further charge related to the making of a false tatement for the purpose of obtaining a passport ast September. A clergyman of Upper Marylebone-treet said he had certified an application for a passport on behalf of the accused, who had described himself as a physician and surgeon. and had declared hat there had been no change in his name. A detective-inspector stated that the accused had said o him: "I have been known as Williams for five years; as you know, my name is Flaxman."

The accused has reserved his defence, and bail has been allowed.

A Guaranteed Cure.

Advertisers who, to put money in their pockets, offer extravagant and ridiculous guarantees in respect of their goods, cannot complain if a customer occasionally takes them at their word. This happened n the recent case of Wood *v.* Lektrik, Ltd., which, f Mr. Justice Rowlatt's judgment is challenged in the Court of Appeal, is sure to find a place in the legal text-books as an illustration of various points of the law of contract. The defendant company advertised "New hair in 72 hours. Lektrik Electric Comb. Great news for hair sufferers. What is *your* trouble? Is it grey hair? In ten days not a grey hair left. £500 guarantee." Mr. Wood, the plaintiff, bought one of the advertised combs and followed the directions ("to get the full benefit you should use it for five minutes"). He used the comb night and morning and occasionally during the day at his office as well, but the guaranteed cure of his greyness proved a failure. He sued for his £500 and won his case, subject to a possible appeal. Some of the defendant company's points seem commercially rather cynical. Their first contention, that the so-called guarantee was a mere flourish, was rejected; the judge took it to be a serious statement. The second contention was an attempt to throw over their own advertisement as something framed by an advertising agency and not authorised by themselves. This slender defence was rejected also; they had paid the agency's bill and had never repudiated the advertisement, but had accepted the profit of whatever sales accrued therefrom. Thirdly, it was suggested that the guarantee of £500 merely guaranteed the *repayment of the price of the comb (3s. 6d.) if the* customer wanted his money back. It appeared that in other instances the advertisements had contained a coupon explaining this remarkable limitation; but, as there was no such coupon in the announcement which attracted Mr. Brown, the suggested limitation was inoperative. Next the defendants said there could be no valid legal contract if there was impossibility of performance. With unusual candour they adopted the position that their comb could really never do what the advertisement promised on its behalf. They correctly argued that no legal consequences arise if someone promises the impossible; but unfortunately the advertisement expressly precluded the idea of impossibility. The combs, it said. were used by *all grades of society, including Royalty*; "not one has failed to do everything we claim for it." Moreover, the advertisement contained a picture of a man living at Forest Hill with his statement that his hair was very thin and going grey, but on the tenth day the greyness had gone entirely; "that Lektrik comb of yours has done the trick." Lastly, the defendants alleged that the plaintiff had not used the comb properly and that anyhow he had not proved that he had not got fresh hair growing from the roots. The judge was unimpressed by these arguments also. He held that the comb had failed in its operation and that the plaintiff, having complied with the advertisement, had made a valid contract and was entitled to the guarantee of £500.

Mr. Justice Rowlatt is known as a judge who decides upon first principles, and is but little swayed by the citation of leading cases. There is, as it happens, a leading case on the law of contract—Carlill *v.* Carbolic Smoke Ball Company—which is closely parallel. Some 40 years ago, when influenza was a greater novelty, a firm advertised the merits of its carbolic smoke ball. and offered £100 to anyone "who contracts the increasing epidemic influenza colds, or any disease caused by taking cold, after having used the ball three times daily for two weeks according to the printed directions." Mrs. Carlill used the smoke ball for several weeks, but contracted influenza. She sued for her £100 and won. The defendants said there was no contract because the firm had not been notified of the acceptance of its offer. The court held that the case resembled that of a reward offered for the recovery of lost property—anyone who performed the condition must be taken to have accepted the offer without further ado. As in the comb case, the defendants said the advertisement was a mere puff which no reasonable person would take seriously. But the advertisement had announced that the firm had deposited £1000 with the Alliance Bank to "show our sincerity in the matter." The plaintiff's victory in the carbolic smoke ball case was upheld by a strong Court of Appeal. Lord Justice Bowen agreed that ordinarily the acceptance of an offer must be notified to the offerer, in order that the two minds may come together and a valid contract be formed. But a person who makes an offer can expressly or impliedly intimate that a *particular mode of acceptance* will suffice to make the bargain binding. If so, it is only necessary for the person to whom such offer is made to follow the indicated mode of acceptance. The Lektrik comb case was perhaps not so clear a case as that of the smoke ball, where Lindley, L. J., had no doubt that there was "a distinct promise expressed in language which is perfectly unmistakable." Undoubtedly the purchasing public allows for a little licence in the language of advertisements; otherwise the Lektrik Company's liability might be colossal. A director of the company told the court that approximately a million of the combs had been sold, and only four persons had claimed the £500.

Heavy Damages for a Doctor.

At Pembroke Assizes on Jan. 14th damages for slander amounting to £5000 were awarded to Dr. J. H. Owen, of Fishguard, medical officer of health to the Haverfordwest Rural District Council, against Mr. Cyril Hugh Barham, of Letterston, a member of the Pembrokeshire County Council. An injunction was also granted restraining him from repeating the slander. Mr. Barham tried to justify what he had said, but the judge told the jury that there was no evidence justifying the slander, and no proof whatever had been put before the court, by the defendant, of the statements he had made. The jury, after a few minutes' absence, found for Dr. Owen, with the damages stated above. Mr. Chappell, K.C., Mr. T. Carthew, and Mr. G. C. Richards (instructed by Messrs. Le Brasseur and Oakley), on behalf of the London and Counties Medical Protection Society, Ltd., appeared for the plaintiff and Mr. Barham conducted his own defence.

MENTAL DISORDER IN SCOTLAND.

THE seventeenth annual report of the General Board of Control for Scotland covers the year 1930, the first in which the former duties of district boards of control and parish councils were exercised by the county councils and town councils. The Board finds that the new authorities are taking an active interest and that there is every reason to hope that the care of the insane and mentally defective will continue on progressive lines. As a rule the lunacy and mental deficiency functions have been referred to the public health and public assistance committee, either jointly (ten cases) or partly to each (39 cases). They have been delegated to the public assistance committee alone in five cases and to a joint public health and lunacy and mental deficiency committee in one case.

Work of Voluntary Societies.—In the old days the vote of the General Board of Control included a sum of £750 towards the work of the societies assisting and supervising mental defectives outside institutions. These societies are of the utmost value. Supervision is carried out tactfully and unobtrusively, and children notified as incapable of receiving further benefit from instruction in a special class or school are followed up, and helped, as far as possible, in daily occupation centres. The associations also keep in touch with children over 16 discharged from special schools and classes. The Board was anxious that the voluntary associations should not have their work hampered in any way under the new Act, and issued a special circular to town and county clerks stressing the importance of maintaining the work, on account of its value to the defectives and of the economy it effected to the local authorities in reducing the necessity for institutional treatment. The local authorities were urged to ask the Department of Health to pay their contribution to the voluntary associations out of the amount payable as the general exchequer grant. The response of the local authorities was not, however, satisfactory, and the Board made a scheme under Section 64 of the Act. The Board also expresses the opinion that local authorities should have specific statutory powers to provide day occupation centres for defective children.

The report includes a brief review of the treatment of the mentally afflicted in Scotland, stressing especially the introduction and development of hospital care and nursing followed by occupational therapy. The great improvement in physical health has undoubtedly played its part in the improvement in mental health. It must be admitted, however, that this improvement is not reflected in the table given in the report; it appears that the recovery-rate in the quinquennium ending 1864 was 37 per cent. and in those ending 1874 and 1884 it reached as high as 41 per cent., while in 1930 it was only 33·9 per cent. The death-rate likewise was 8·2 per cent for the five years ending 1864 and sank as low as 7·7 per cent. in the five years ending 1879. For 1930 it was 8 per cent. The report attributes this statistical anomaly partly to the increase in voluntary patients, for whom no statistics are available.

The Board lays considerable stress upon the importance of the factor of generous accommodation, measured in floor space rather than in cubic space, as contributing to the general health of patients. When asylum accommodation was severely congested during the war, the death-rate rose considerably and the recovery-rate dropped. The Board considers that each patient should have 30 sq. ft. of floor space in the day-room, 60 sq. ft. in the dormitory, and 90 sq. ft. in hospitals and single rooms. This standard is often found too high in institutions where economy has reigned, during the war and post-war years, while the number of patients has steadily increased. The Royal Asylums alone show a surplus of accommodation. In the district asylums there is little if any margin and often a serious deficit on the Board's minimum. The overcrowding is partly due to the presence of over 2000 mental defectives in asylums for the insane and also to the presence of patients who could quite satisfactorily be boarded out with suitable guardians or in less expensive types of institution. The Board hopes that the demand for asylum accommodation may be decreased, first, by putting these patients in suitable accommodation, and secondly, by increasing the number of observation wards in poor-law hospitals for the treatment of mild and incipient mental disorder without certification.

On Jan. 1st, 1931, there were 19,241 insane persons in Scotland, an increase of 182 during the year. Voluntary patients admitted during the year numbered 734 and there were 972 such persons under care on Jan. 1st. There were 1406 pauper and 71 non-pauper patients provided for in private dwellings with the sanction of the Board, a decrease of 60 on the previous year. The visitors report that these boarded-out patients are extremely well and tactfully treated, although some of the guardians are quite aged persons. The death-rate of these patients was 1·27 per cent., and there was only one case of tuberculosis among them all. They have the benefit of light work on the crofts and farms, and it appears to be certain that no patient is overworked except in domestic service. The system seems to be equally successful for the defective, except that these patients are apt to be unsettled as a result of ill-judged letters or visits from relatives and also as a result of seeing other persons being paid a wage or a dole. One defective actually applied for discharge from certificate in order that he might apply for Government relief! All the visitors urge that greater advantage ought to be taken of this eminently satisfactory method of care.

On Jan. 1st there were 3299 certified mental defectives on the registers of the Board, an increase of 225 on the preceding year. During 1930, 112 aided mental defectives were certified and placed under guardianship.

OASTS RESORTS CONFERENCE AT TORBAY.

: CONFERENCE of medical men and others
ested mainly in the south-western coastal health
ts took place at the Paignton Palace Hotel
. Jan. 15th to 17th, under the chairmanship of
Alfred Goodson. Many medical officers of
th and practitioners from seaside towns in
on, Cornwall, and Somerset took part in the
tings, Lieut.-Colonel R. H. Elliot, Dr. Fortescue
, and Dr. W. S. C. Copeman being present on
alf of the London Provisional Committee on
st Resorts. The conference was largely attended
included representatives of the railway, hotel,
entertainments organisations, and those present
ned to be keenly alive to the importance of
ing immediate means to unite in a common
rt the various interests concerned. The merits
possibilities of the health and holiday resorts of
British coasts at all seasons were laid before the
ference in a series of addresses.

he aims of the Provisional Committee, as set forth
he memorandum presented to the meeting at the
titute of Hygiene in London on Jan. 11th, were
ussed and approved: These are as follows:—

To formulate the medical case for the British marine
th resorts in the prevention and cure of disease, and
differentiate on a scientific basis the various regions
places of the coast.

. To make this information known to the medical
ession and the public.

. To encourage due provision of medical requirements,
h as diet-prescriptions, adequate open-air shelters,
hs, and other treatment facilities, improved and reason-
e hotel accommodation, and other amenities.

. Whilst fully recognising the admirable progress effected
many municipal authorities and local medical associa-
ns on the coast in devising and providing such facilities,
coördinate and assist the efforts of these and other bodies,
where necessary to encourage the initiation of new
k.

. To consider the formation of a medical organisation
ich shall link together medical men on the British coast.

. As soon as practicable to establish in London a Central
reau for distribution of approved literature and for
nishing the necessary assistance, advice, and information
the public and to medical men—the British Spas Federa-
n and other organisations responsible for the health
orts of the country to be invited to coöperate in the
anisation of this Bureau.

. To promote regional conferences in the various areas
the coast.

. At the proper time, as may seem fit, to change the
me and enlarge the scope of the Association (the British
ast Resorts Association), in coöperation with organisa-
ns representing the spas and other British health resorts.

Members of the Committee pointed out that no
nd of medical or other organisation has hitherto
en framed to make known the attractions of the
ter ring of health and holiday resorts on the coasts
the British Islands; the spas were already organised.
ther speakers emphasised the educational value of
organisation dealing specifically with the coast
sorts, and of a permanent medical advisory body
London, and the need of a central bureau which
ould obtain the necessary medical data from the
calities and collate and edit the material for the
idance of the profession and the public.

Many speakers drew attention to the need for
proved and more reasonable accommodation at
aside places, also to the importance of abolishing
e unnecessary restrictions which at present hampered
eir development.

The following resolution was unanimously passed:

"That this Conference considers it a matter of urgency
at there should be formed a British Coast Resorts Associa-
on, and earnestly recommends to the Committee appointed at the meeting held under the chairmanship of Lord Riddell at the Institute of Hygiene. on Monday, Jan. 11th, 1932, that it should proceed to its establishment with the least possible delay."

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

PROGRESS OF PUBLIC HEALTH.

THE report of the Department of Local Government and Public Health of the Irish Free State for 1929–30, recently issued, records a steady and satisfactory progress as regards activities bearing on health. The death-rate was 14·59 per 1000 of the population as compared with 14·84 for the preceding decade. The highest death-rates were in the county boroughs, the lowest in the almost purely rural areas. The death-rate from the principal epidemic diseases in county boroughs and towns with a population of over 10,000 was 0·96 per 1000 of the population, in contrast with 0·53 for the whole country and 0·38 for the rural areas.

In regard to the principal epidemic diseases typhus appears to have almost disappeared, only eight cases being notified during the year; on the other hand, there was an increase in enteric, 385 cases being notified, as compared with 304 in the previous year. The increase was almost altogether due to a severe outbreak at Carrick-on-Shannon, causing 80 cases, and due to water-borne infection. There was also an increase in diphtheria, which was nearly counterbalanced by a diminution in scarlatina. Immunisation against diphtheria has been extensively carried out in several counties.

In the year under review five county medical officers of health were appointed, six being already in office. (The number has since been considerably increased.) There has been a slight improvement in the maternal mortality associated with childbirth, the rate per 1000 births being 4·10, whereas the rate for the previous decade was 4·88. There is, however, an appalling mortality under this head in certain rural areas, reaching 7·78 per 1000 in Queen's County and 7·12 per 1000 in County Antrim. The report makes the definite statement that "the delay in appointing county medical officers of health . . . must be regarded as a contributing factor to the excessive mortality associated with childbirth in these counties." The infant death-rate showed a slight increase over the previous year, 70 per 1000 compared with 68, the increase being mainly due to the prevalence of respiratory diseases. The county boroughs still show a very high infant mortality—Limerick 116·7, Waterford 110·3, Dublin 106·2, and Cork 85·2. The mortality among illegitimate children is about five times that among legitimate children.

There was considerable development of medical inspection of school-children during the year, and this branch of preventive medicine has proved popular with the public, and has gained the coöperation of both parents and teachers. It is noted that, generally speaking, school hygiene and sanitation are in a backward condition, especially in rural districts. The atmosphere is often observed by the inspectors to be vitiated, clean sanitary accommodation to be lacking, lighting and heating insufficient, floors and windows dirty, and playgrounds inadequate. Increased use has been made of the School Meals Act. The death-rate from tuberculosis in 1929 was the lowest yet recorded for the country—1·32 per 1000 of the population. It is noted that so rapid has been the expansion of anti-tuberculosis activity in recent years that the number of patients under treatment under the several public schemes has doubled between 1923 and 1929.

Dealing with the administration of "medical charities," otherwise the dispensary medical service, the report states that in almost all counties graded scales of salaries for the medical officers have been adopted. It also states that use is being made by medical officers of the facilities given them for attending post-graduate courses. The facilities are hardly very attractive at present, as the medical officer going on study-leave has not only to pay all his expenses but also to provide a substitute at his own cost.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

SURPLUS BEDS IN HOSPITALS.

THE former shortage of beds in municipal hospitals in Berlin has now become a surplus, the number of in-patients having greatly decreased. The same position is reported from other cities, notably Dresden and Hanover, where respectively 39 per cent. and 26 per cent. of the available beds are unoccupied. One reason is that the Krankenkassen in order to save expenses are sending fewer patients to hospital than they used to do. Another reason is that the medical men engaged in club practice have less private practice than formerly, and are thus in a position to attend more club patients at home instead of sending them to hospital. Moreover, the fear of losing their employment has led many of the working people to prefer to be attended at home. The municipal authorities of Berlin as long ago as 1930 closed two hospitals which were reopened temporarily during the epidemic of influenza in January, 1931, but were closed again afterwards with two other municipal hospitals containing 2400 beds. In spite of these closures 15 per cent. of the beds in municipal hospitals are still empty, and even those private hospitals in which many wards have been closed for want of means are not full.

A NEW PATHOLOGICAL MUSEUM.

The Pathological Institute of the municipal Friedrichshain Hospital has been reorganised as a pathological museum. This museum was planned many years ago by the late Prof. Virchow. The large quantity of pathological specimens collected since the opening of the big municipal hospital in 1874 has now been systematically rearranged. The sections devoted to specimens of tuberculosis, cancer, syphilis, dysentery, and rickets, and of injuries, especially those caused by the war, are particularly complete; the total number of specimens amounts to 5000. In his opening address Prof. Pick, the director of the museum, pointed out the value of autopsies in confirming diagnosis in medico-legal work, and for insurance statistics as well as in the study of heredity problems.

ACUTE QUININE POISONING.

A patient who had attempted suicide by taking quinine was recently admitted to the Neukölln municipal hospital. Dr. Goldmann states that a man was found unconscious in a street with two bottles labelled sulphate of quinine in his pocket. The stomach having been washed out at a first-aid station, he was conveyed to the hospital in a state of deep com The urine contained albumin with casts and re blood-cells. Under camphor and strychnine injec tions the patient recovered after 24 hours, but wa completely blind and nearly deaf. His hearin capacity gradually became normal, but he complaine of tinnitus in the ears, of headache, and of palpitati of the heart. Six days after the poisoning hi vision began to reappear, but the field of vision wa diminished and hemeralopia developed. Four week after admission he was discharged from the hospita and attended as an out-patient in the ophthalmologica clinic of the university. Two months later his sigh was normal, but the field of vision still diminishe and the hemeralopia unchanged. Chemical examin tion proved that he had swallowed 18 g. of quinin sulphate.

STORAGE OF RADIOGRAPHIC FILMS.

New regulations on the storage of radiograph films have been issued by the government. Accordi to those regulations films must not be kept in hospit wards, even in special cabinets. Smoking in roo where films are preserved is strictly prohibited, a the doors of storing rooms must always be kept clo No open fires are allowed and a fire extinguis must be kept in the room. Special regulati apply to film rooms in which more than 150 kg. films are stored. They must be kept immediat under the roof and the heating, electric installati and lightning conductors must conform to cert conditions. In rooms containing from 5 to 150 of films the films must be kept in special cabi and the precautions to be taken against fire explosion are set out in detail. A collection of f under 5 kg. in weight must be stored at a distanc at least 1 meter from the nearest heating appara The above regulations do not apply to so-called inflammable films.

MALNUTRITION OF CHILDREN.

Dr. Heimann has made a report to the Be Society for Public Health on an investigatio children recommended for a visit to a muni health resort. The children came from a dis of Berlin inhabited especially by working- people. Though they had no special disease weight and their height was far below the nor Apparently the wages of the parents do not cove cost of food and housing, and the childre unemployed persons suffer additional privat Housing conditions proved very unsatisfac In 53 cases four persons lived in a single room at and in some cases 14 persons in three rooms, so conditions of gross overcrowding existed. Dr. mann found the children's development to be reta The number of children sent to holiday resorts had to be much restricted, and since the maxi stay is six weeks no marked improvement is t expected.

TREATMENT OF ERYSIPELAS BY IODINE.

Dr. Meyerhof reports on the results obtained i Hamburg General Hospital by the treatmen erysipelas with tincture of iodine. The whole of the erysipelas and its surroundings were cov with a thick layer of a 10 per cent. tincture of io The application must be so dense that the skin ass a chocolate-like colour and must be renewed tw day until the fever subsides. Among 88 cases tre in this way the fever disappeared after only on two days in 66 per cent., the average duration of fever without treatment being six days. E cases died from complications.

CORRESPONDENCE

TISTICAL EXPRESSION OF RESULTS IN MEDICAL RESEARCH: TWO COMMON PITFALLS.

To the Editor of THE LANCET.

IR,—The statistics required for the convenient rding of results in medical research work are not complicated kind, but it not infrequently happens the interpretation of these statistics is rendered e the easier by an inappropriate method of ulating percentages.

et us take, as an example from laboratory work, investigation of the accuracy of a particular . How often are the results couched in the form, so many cases, so many positives were obtained which so many were incorrect." Or this may be reviated into, "So many per cent. of the positives e false positives." If left in that form, what do se results convey? Very little. For if, for mple, we are told that "5 per cent. of the posi- es were incorrect," it subtly suggests a necessary tion between the number of false positives and total number of all positives. But any relation ween them is really no more than an accidental . The true relation to be expressed is the one ween the number of cases giving *false positives*— , cases failing to give correct negatives—and the *l number of cases that should have given negative ults.* A reductio ad absurdum will make the tter clear. Suppose in the investigation of a test syphilis that 100 non-syphilitic cases—and only se cases—were tested, and suppose further that positive results (therefore *false* positives) were ained, would we return our results as "100 per t. of the positives were incorrect"? The absurdity bvious. What we really should say is "5 per cent. the non-syphilitic cases were incorrectly returned positive."

The second source of misunderstanding lies in the ference between statistical material obtained from perimental series and the material likely to occur actual practice. Again let a hypothetical example istrate the difficulty.

Two tests for syphilis, Test A and Test B, are der investigation, and the number of correct and correct results are expressed as percentages in the nner suggested above. The actual criterion of curacy, and the means of deciding which cases are philitic and which not, need not concern us here; may be based on clinical material, or the histories the cases, or the collateral use of other tests as ntrols. Let us suppose the results worked out as llows :—

rrect results.	Syphilitics.	Non-syphilitics.	Average.
ith Test A..	93 per cent. ..	99 per cent. ..	96 per cent.
" " B..	98 " " ..	98 " " ..	98 " "

Let us not run away with the idea that Test A will eld more errors than Test B. For Test A will only eld more errors than Test B *as long as the number of philitics and non-syphilitics are equal.* But will ey ever be equal in actual practice? Most likely t. And if these tests are investigated for the urpose of applying them as a routine to all such ses as are found in ordinary practice, or in a general ospital, or in a mental hospital (to mention a few ssibilities), it is more likely that the material will clude, not 50 per cent. of syphilitics, but something ke 10 per cent.

On that assumption of 10 per cent. syphilitics, it would mean that in a series of 1000 cases, the errors with Test A would be 7 per cent. of 100, plus 1 per cent. of 900, that is, 16 cases, or 1·6 per cent. Those with Test B would work out at 2 per cent. of 100, plus 2 per cent. of 900, that is, 20 cases, or 2 per cent. This shows that *in actual practice* Test A would yield, not more, but *less* errors than Test B.

All this is elementary enough, and one would hesitate to mention these pitfalls were it not for the hope that such mention might assist towards a greater uniformity in recording results. It may be argued that where detailed figures are given it is an easy matter to work out the required facts for oneself; but in these days of increased and rapid output of research, anyone who has to work through many references in a short while would be considerably assisted were the statistical results invariably given in a form that would express the true state of affairs, instead of one that is not only of little value but which may, to the unwary, prove misleading.

I am, Sir, yours faithfully,

J. ERNEST NICOLE.

Winwick Mental Hospital, Jan. 17th, 1932.

THE CEREBRO-SPINAL FLUID PRESSURE IN CASES OF HEAD INJURY.

To the Editor of THE LANCET.

SIR,—At a discussion at the Royal Society of Medicine on the Diagnosis and Treatment of Head Injuries reported in THE LANCET of Dec. 12th, 1931, it seemed to me that quite an unwarranted degree of importance was attached by most of the speakers to the pressure of the cerebro-spinal fluid. The matter is raised again by Dr. C. M. Hinds-Howell in the paper on Trauma and the Nervous System which appeared in THE LANCET last week.

At the discussion one of the opening speakers said that he decided not to operate on a case in which he suspected intracranial hæmorrhage, because the cerebro-spinal fluid pressure was not markedly raised. As long, however, as there is no interference with the circulation of the cerebro-spinal fluid, mere increase in the volume of the other intracranial contents does not produce any significant rise in the pressure. Thus, though a large hæmatoma may be present the cerebro-spinal fluid pressure may remain within normal limits. Another closely related fact is that *local* cerebral compression (by which hæmorrhage often causes its symptoms) is independent of the general intracranial pressure. The following example from my own experience illustrates this point. In a fatal case a large subdural hæmatoma compressed the underlying cerebral hemisphere, causing gross deformity; yet the general intracranial pressure was only 80 mm. Aq. In a case in which subarachnoid hæmorrhage resulted from a fall and produced a clinical picture of local cerebral compression, the cerebro-spinal fluid pressure was under 180 mm. Aq. In another case of subdural hæmatoma, in which depression of the cerebral hemisphere was seen at operation, the pressure was 150 mm. Aq.

In cases of head injury the pressure is often raised when there is no hæmorrhage and it is apparent from what I have said that it may be within normal limits and even low when hæmorrhage is present. The pressure reading has therefore little diagnostic value in the very cases in which, because of the necessity for operation, help in diagnosis is most required.

has been the expansion of anti-tuberculosis activity in recent years that the number of patients under treatment under the several public schemes has doubled between 1923 and 1929.

Dealing with the administration of "medical charities," otherwise the dispensary medical service, the report states that in almost all counties graded scales of salaries for the medical officers have been adopted. EXTRACT OF SUPRARENAL CORTEX.

To the Editor of THE LANCET.

SIR,—In a paper on three cases of Addison's disease treated with an extract of suprarenal cortex which appeared in THE LANCET of Jan. 16th, Dr. Benham and his colleagues state that the extract of suprarenal cortex used in the treatment contained definitely a small trace of protein amounting to not more than 10 mg. per 100 c.cm.

I would like to point out that the evidence for the presence of even so small a quantity of protein in Eucortone (A. & H.) (which was used in the treatment of the above cases) is very doubtful. In the first place the method of extraction with 80 per cent. alcohol followed by benzene makes it extremely unlikely that protein, even in traces, would be present. Swingle and Pfiffner[1] stated that their extracts gave negative results with the biuret, Hopkins-Cole, Molisch, and Liebermann-Burchard reactions, but positive with the xanthoproteic, Millon's, and alkaline phosphotungstate reactions. The latter are attributed to the presence of phenolic decomposition bodies of adrenalin. Eucortone gives exactly the same results as the above. Moreover, when eucortone is salted out with ammonium sulphate, the small amount of precipitate obtained gives even more indefinite results for the presence of protein. The total nitrogen in eucortone has never exceeded 0·02 per cent., and is usually about 0·01 per cent.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdr. J. S. Orwin is placed on the retd. list with rank of Surg. Capt.

The following appointments are notified: Surg.-Comdr. H. F. Briggs to R.A.F. Hospital, Portland; Surg. Lt. F. M. Duthie to *Aphis*.

ROYAL ARMY MEDICAL CORPS.

Capt. G. de N. U. Somers relinquishes his temp. commn.

Capt. T. W. Davidson from the secd. list is restd. to the estabt.

TERRITORIAL ARMY.

Maj. D. H. Coats, R.A.M.C., to be Divl. Adjt., 51st (Highland) Div., vice Maj. W. Campbell, R.A.M.C., vacated.

Capt. J. G. E. Vachell, R.A.M.C., to be Divl. Adjt., 49th (W. Riding) Div., vice Maj. E. J. S. Bonnett, R.A.M.C., vacated.

Lt. C. de W. Kitcat to be Capt.

ROYAL AIR FORCE.

Air Commodore H. V. Wells has been appointed P.M.O., Air Defence of Gt. Britain.

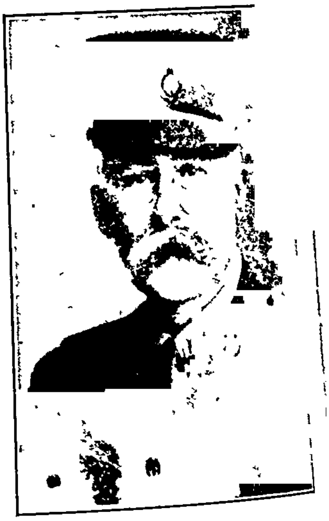
FOOD EDUCATION SOCIETY.—Dr. Richard Ackerley will lecture on Diet and Personal Hygiene at 29, Gordon-square, W.C.1, at 5 P.M., on Wednesdays, Feb. 10th, 17th, and 24th. Tickets may be had from the Hon. Secretary of the society, at that address.

OBITUARY

JAMES CALVERT, M.D., B.Sc., F.R.C.P.,

CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITA

WE recorded last week the death of Dr. Ja Calvert on Jan. 13th, which occurred unexpect at the age of 76, and has left a deep sense of on many friends.



DR. JAMES CALVERT.

[*Photograph by Elliott & Fry*

James Calvert, the son of the late Edward Ca of Stonerigg, Cumberland, was educated priv and proceeded, at a rather later age than is usual with students, to the medical school at St. Bartholomew's Hospital, having graduated as B.A., B.Sc., in the University of London. He was very successful in the school, and obtained first-class honours in the examination for the M.B. Lond. in 1885, and proceeded as early as possible to the M.D. degree. He filled the usual junior appointments at his hospital, and in particular had a long experience as a pathologist and in the post-mortem room. In 1902 he was electe assistant physician and soon afterwards lecturer o materia medica, pharmacology, and therapeutic He thus established a reputation among students a practical teacher, while his quiet humorous mann appealed to them. In 1895 he was elected F.R.C. and in the following year he became Warden of t residential college at St. Bartholomew's, a positi which he filled with great success for a consideral period. In 1913 he became full physician to hospital and lecturer on medicine in the medi school. He had in the meantime been elec physician to the Royal Chest Hospital in the Ci road, an appointment which influenced his prac in a marked manner. He was a thoroughly g clinician, making full use of his accurate knowle as a morbid anatomist and his special familia with diseases of the chest, and both as lecturer bedside teacher achieved a sound reputation wi and without the walls of his own hospital. He appointed examiner in medicine at different ti to the Universities of London and Liverpool, at the Royal College of Physicians of London, w he held the post of censor.

On the outbreak of the war Calvert became se medical officer and chairman of the medical b at the 1st London General Hospital, at Camber with the rank of Lieut.-Colonel R.A.M.C.(T.). discharged the duties with marked efficiency, in this capacity was appointed to conduct an in into a serious outbreak of influenza which occurr the Crystal Palace at the end of 1918; about men out of an average number of 5600 statione the Palace having sickened with the disease, 1 ied from associated pneumonia. At the the war, he received the C.B.E. for his

rt was an infrequent writer, but his contribu- the literature of the two sides of his professional iich personally interested him were of practical He wrote the article on Prescribing in son's and Collier's Index of Treatment; t. Bartholomew's Reports he was an occasional itor, while clinical reports made by him will d in the Transactions of the Clinical Society, he old Royal Medical and Chirurgical Society. the duties which he undertook Calvert was rthy, while he discharged them with extreme tion, his slow manner and quiet humour being eristic of him. He was in hospital affairs irable colleague.

Calvert married Therèse, the eldest daughter ate Mr. John Smithers, and one of his daughters . Sir Eric Stewart Taylor, M.D., the son late Sir Frederick Taylor, formerly President Royal College of Physicians of London.

HUGH S. DAVIDSON, O.B.E., M.B., F.R.C.S. Edin.

Mr. Hugh Davidson, who died on Jan. 5th after curling at an ice-rink, was one of the most competent and popular members of the medical profession in Edinburgh. He was a good shot and an adept in billiards and tennis, and the physical dexterities that drew him to those games were an asset in his training and practice as a gynæcological surgeon. He graduated as M.B. in 1903 with first-class honours, and became F.R.C.S. Edin. in 1906. He studied for a period at Prague and at Vienna. He had the usual "resident" experiences of a specialist in training, and at the time of his death had become gynæcologist to the Royal Infirmary, physician to the Royal Maternity and Simpson Memorial Hospital, and to the Women's Hospital in Archibald-place. Formerly also he was on the staffs of the Deaconess Hospital and the Chalmers' Hospital. Two years ago he held office as President of the Obstetrical Society. He was recognised as a clever diagnostician. a sound operator, and an excellent teacher.

Kent.

A. Greenwood says 1930 was the first year in the infant mortality-rate has been lower in the than in the rural districts. He is disappointed he figures for maternal mortality. The puerperal rate was the highest since 1926, and the rate other accidents, &c., the highest since 1927. e V.D. clinics 35 per cent. of the syphilitic 3 per cent. of the gonorrhœa patients defaulted. is a tendency to make more use of the public ance hospitals, and in some areas accommoda- ias been found for acute cases by the transfer iers to the infirm wards of other institutions. ianges have been made in the out-relief system. cial scheme is in force in Dartford by which the formerly paid to the district medical officers ortioned among eight practitioners in accordance the work done. The poor-law institutions are the mixed type. The Tenterden institution been appropriated for mental defectives. work of the county pathological laboratories continues to increase, and the scheme for the treatment of crippled children operates satisfactorily. Mr. A. L. Moreton, F.R.C.S., who was in charge of the 80 beds at the Alexandra Hospital and of four out-clinics shows how the work has developed and increased. He advocates more frequent clinics, so that classes in remedial gymnastics and massage may receive more attention; and says the number of beds at the hospital should be increased. There is usually a waiting-list of some 20 to 40.

There has been a development during the year of antenatal clinics which are mostly staffed by a local practitioner with the assistance of the health visitor and district nurse for the area. These clinics now number 14. In 27 of the 39 sanitary districts which comprise the county council's child welfare scheme, whole-time health visitors act as infant life protection visitors and in the remaining 12 this work is done by district nurses or officers of the public assistance committee taken over from the guardians. About 418 children are being maintained by 284 foster-parents. During the first nine months it was found necessary to remove six children from two foster-parents to places of safety.

Dr. S. N. Galbraith (S.W. Kent United Health Area) says that farms near Maidstone and Tonbridge made increased use of home-pickers of hops and that with cheap bus transport this development may increase. He says there were very few improvements undertaken in the camps and that the week-end visitors remain a great problem. The transmission of infection by hoppers remains a problem. One family of eight, all suffering from small-pox, travelled down last year by ordinary train. The medical care of the hoppers is mostly carried out by voluntary organisations, and a scheme has been devised for linking these organisations in a coördinated plan and for dividing the large hop-picking area into sub-districts. Dr. Greenwood discusses the housing returns from the districts. The closing orders were fewer and the houses demolished more than in the previous year. The shortage of houses is estimated to be considerably greater than in 1929.

A conference of the medical officers of health and sanitary inspectors of the districts was held at Maidstone in March, to discuss the possibility of aiding employment by water-supply schemes, and as a result schemes are proposed in various districts.

Durham.

Dr. C. Franks in his first report says that many of the vital statistics are the most satisfactory on record.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Monday, Jan. 25th.—8 P.M., Odontology. Casual communication: Mr. J. Edgley Curnock: Osteomyelitis of Jaw—Spontaneous Fracture. Paper: Mr. E. C. Sprawson: Preliminary Investigation of the Influence of Raw Milk on Teeth and Lymphoid Tissue.

Wednesday.—5 P.M., Comparative Medicine. Discussion: *B. welchii* Infections in Animals and Man. Opener: Major T. Dalling, followed by Mr. A. D. McEwan, Dr. Muriel Robertson, Mr. B. W. Williams, Prof. C. C. Okell, and others.

Thursday.—8.30 P.M., Urology. Mr. Ralph Thompson: The Treatment of Urinary Calculus. (Presidential address.)

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

Monday, Jan. 25th.—8.30 P.M., Discussion on the Causation and Treatment of Essential Hypertension, to be introduced by Dr. Geoffrey Evans and Dr. G. Arbour Stephens.

MEDICO-LEGAL SOCIETY.

Thursday, Jan. 28th.—8.30 P.M. (11, Chandos-street, Cavendish-square, W.), Dr. L. A. Weatherly: The Liberty of the Subject from the Medico-legal Aspect. To be followed by a discussion.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street, Cavendish-square, W.

Friday, Jan. 29th.—8.30 P.M., Mr. David Lees: Paper on Observations on Syphilis of the Nervous System and its Treatment. A discussion will follow.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

Monday, Jan. 25th, and following Wednesday and Friday.—5 P.M., Sir Arthur Keith: Malformations of the Human Body from a New Point of View.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, Jan. 25th, to Saturday, Jan. 30th.—Medical Society of London, 11, Chandos-street, Cavendish-square. Lectures on Endocrinology by Dr. W. Langdon Brown, at 8.30 P.M. Mon., The Parathyroids and Calcium Metabolism. Fri., The Adrenals and the Gonads. Lectures on Treatment, Wed., at 4 P.M., by Dr. B. T. NOTES, COMMENTS, AND ABSTRACTS

POST-VACCINAL ENCEPHALITIS:

TS ASSOCIATION WITH VACCINATION AND WITH POST-INFECTIOUS AND ACUTE DISSEMINATED ENCEPHALITIS.*

BY PROF. RICARDO JORGE,
ESIDENT OF THE PUBLIC HEALTH COUNCIL OF PORTUGAL.

Principal Characteristics.

ost-vaccinal encephalitis appears to be an infection cent date. Its beginning, or rather our knowledge t, dates from the year 1922. The earliest cases discovered in England then, and independently Holland in 1924. Other and older cases were hwith recalled as, on a retrospective diagnosis, ing been certain or at least probable examples he same condition—for example, that of Turnbull, g back to 1912, while others still earlier were llected by doctors in Switzerland, Germany, and where. These "retrospective" cases do not, ever, go further back than the closing years of past century.

t has not been possible to find any clear indica- is of complications of an encephalopathic nature owing vaccination during the long series of years ch succeeded Jenner's discovery. Gins (personal munication) has come across a vague mention nervous complications in the works of an early cinator, Sacco. Kaiser has recently cited an ial report in Bohemia in 1801, which alludes to vous reactions following Jennerian vaccination.[1] past times certain special commissions for the study he dangers of vaccination were in session in England considerable periods; and a most persevering minute inquiry of this kind was made on complica- is observed after vaccination without the discovery cerebral involvement (Royal Commission on cination 1889–1896). A similar inquiry in Holland 1902, to which 90 per cent. of the doctors in the ntry contributed, reported as nervous complica- is following vaccination only two cases which e tuberculous meningitis (Jitta).[2] It is, of rse, quite possible that one or two isolated cases y have escaped detection, but it seems unlikely t epidemic waves, such as those which have urred in England and Holland, could have passed recognised.

Until wider information is at our disposal we must clude that encephalitis as seen at the present day not been contemporaneous with the practice vaccination, which has been world-wide for nearly years without revealing attacks on the nervous tres of those vaccinated. Hence, both on presump- n and in practice, here is a new disease and one recent date.

DISTRIBUTION.

Post-vaccinal encephalitis has a very irregular geo- aphical distribution (vide previous report of 1930).[3] ny countries have not been affected; in them, spite of careful inquiry, not a single case has been served. The countries which have suffered the st, but now to much less extent than in previous ars, are England and Holland, while Austria, rmany, Norway, Sweden, and the United States ve supplied an appreciable number of cases. Then llow countries with rare sporadic cases, and, finally hers, where all that can be said is that the statistics the malady are merely represented by a zero.

How are these topographical differences to be explained—maximum incidences in one place and no incidence in another? The difference in the age selected for vaccination helps to explain the inequality of distribution; encephalitis will be found where the primary vaccinations are, as a rule, performed at school age—the period which is most susceptible as regards encephalitic invasion.[3]

Even in England and Holland, however, the chorographic distribution of cases is most irregular, and one can only surmise from this that here is one more example of what is usual for other epidemic infections. Even in countries which have suffered most from it, the disease is rare and the attack rate forms an infinitely small percentage, whether in relation to the general population or to the number of persons vaccinated.

NEUROLOGICAL MANIFESTATIONS.

Post-vaccinal encephalitis has its own neurological characteristics but at times assumes polymorphous forms. These morbid characteristics continue to be manifest and, especially in the English series, the majority of cases diagnosed as post-vaccinal encephalitis are still in their clinical aspect identical with the cases originally described. The condition is fundamentally monotypical, repeating itself in case after case. Its evolution is that of an acute disease which, in cases of recovery, is quickly over without leaving any complication. Sequelæ are relatively rare by contrast with encephalitis lethargica and with other varieties of meningitis and encephalitis.

When one looks at these happenings as a whole, it appears that there have been more exceptions to this general homogenicity of symptoms recently; in other words, that the clinical manifestations and the nature of the syndrome have become more variable. If post-vaccinal encephalitis was originally monotypical it has escaped from its exact boundaries and is showing definite tendencies to variation. One may, therefore, have to add to the original picture localised paralyses, hemiplegias, convulsions, polyneuritis, &c., and these complications at times introduce serious difficulties in the diagnosis and the clinical typing of the disease. However this may be, it is not enough merely to attach this label whenever nervous complications appear in a vaccinated case. The data obtained should undergo careful sorting with a view to eliminating infections which are associated with a known or likely cause, such as syphilis, cerebro-spinal meningitis, tuberculous meningitis, purulent meningitis, encephalitis lethargica, poliomyelitis, &c. Grey and Whittaker[4] have reported two cases of staphylococcal septicæmia in which post-vaccinal encephalitis had been diagnosed from which, following the Rolleston Commission, they concluded that the bacteriological investigations necessary to exclude septicæmia are never to be forgotten in the examination of these cases. Priest[5] reports a similar case which one would have looked upon as post-vaccinal encephalitis if a blood culture had not revealed the presence of *Staphylococcus albus*. Certain cases occurring in Holland thought to be post-vaccinal encephalitis have been found on autopsy to be due to some entirely different condition (communication from Mr. Jitta). And even when all these exclusions have been made there still remain some cases which are indefinite or doubtful owing to the absence of sufficient signs or other reasons.

Gins[6] would like to see a most rigorous distinction established—the diagnosis of encephalitis to be reserved for cases in which cerebral inflammation has been established histologically, or for those which are followed by sequelæ indicative of encephalitis. All other conditions should be called *nervous complications*. Since autopsies are rare and sequelæ infrequent, the resulting total of proved cases of encephalitis would, on this basis, be decidedly meagre. In our and revaccinated adults, and alsol of patients suffering from nervous troubles after inocuation. Out of 188 samples of blood taken during the course of a normal vaccination, they have verified in 47 instances the presence of the virus from the third to the tenth day. In one vaccinated case the virus persisted until the seventeenth day; it was absent in the revaccinated. The results were negative as regards the mucous excretion of the tonsillar region, which leads one to think that the elimination of vaccine by the throat is not as frequent as Gins believed it to be.

---

* Translation of the substance of a report to the Commission Small-pox and Vaccination of the Office International Hygiène publique by Prof. Ricardo Jorge (Delegate for rtugal), President of the Committee. This report, which s prepared e rapporteur on the subject ir George r Great Britain), was sub- itted to the of the Office International Hygiène publique at its session of October, 1931, and appears the Bulletin mensuel de l'Office International, December, 1931.

It is remarkable that it was never possible to demonstrate the presence of the vaccine virus in 56 samples of cerebro-spinal fluid collected from vaccinated subjects free from complications. But the virus was obtained in two out of five cases with nervous complications, and was also found in the tonsillar region. Hence the deduction that the affection of the nervous centres might be due to an invasion of the cerebro-spinal fluid which has failed in its *function as a barrier to myeloencephalitis.* The facts are not yet sufficient to place this proposition on a firm basis. Moreover, in vaccinated animals the brain harbours the virus, and it can be found in rabbits in the cerebro-spinal fluid even when the vaccinal condition progresses in the normal way. Gins[21] detected the persistence of the virus in the blood and spinal fluid of two human cases on the twenty-fifth and twenty-sixth day. One of these vaccinated persons was suffering from tuberculous meningitis and the other from cerebral syphilis, and the author considers that this departure from the normal might be explained by the delay which these morbid conditions would cause in the elimination of the virus. This question can only be thoroughly examined in the light of further research on the production of encephalitis by the vaccine virus in animals.

EXPERIMENTAL ENCEPHALITIS OF VACCINAL ORIGIN.

Susceptible animals submitted to cutaneous inoculation do not show cerebral complications during or after the evolution of the vaccinal process. Their position is the same as that in the human subject before post-vaccinal encephalitis was known. Observation and experiment have never shown encephalitis in the most susceptible, such as the calf, which provides the lymph of the institutes, or the rabbit which is the laboratory touchstone of vaccinia.

Such exceptions as can be gleaned from literature confirm by their extreme rarity this rule of brain tissue being unaffected by vaccination. We have only found the two following. Van Bouwdijk Bastiaanse,[22] in examining a calf killed 11 days after inoculation, found lesions in the brain similar to those of post-vaccinal encephalitis in man. This single and isolated case is not very convincing. Flexner[23] reports, from a personal communication from C. Rhoads, that two rabbits inoculated with a neurotesticular vaccine which produced severe cutaneous lesions died with marked nervous symptoms—a meningo-encephalitis, confirmed post mortem—whereas the other organs were apparently not much affected.

Normally, and as a general rule, there is no such thing as internal vaccinal metastasis; the brain, like other viscera, remains indifferent to the virus which bathes it. For these organs to be affected there must be direct inoculation of the lymph, and even then the brain often resists the injection. As a successive passages through the brain necessary for the cultivation in its accine of Levaditi. The roduced has characters mation, accompanied f irritation. Do the the histological stamp Kinnershoff, Pondman, and rabbits and monkeys, ammations, the lesions those which appear in the lren following vaccination. Lymphs which have been the cause of litis do not even possess any marked neurotropis several of them were of quite a low virulence and no action on the brains of rabbits. Weston and Fairbrother,[25] following research carried out rabbits in which they produced encephalitis by dire cerebral inoculation, conclude that human and animal encephalitis show altogether different logical characteristics. It has never been to provoke encephalitis by cutaneous inoculation, even after submitting the nervous system to slight trauma. These authors deny that there is a encephalitogenic, or even a neurotropic, property in vaccine virus.

Whatever may be the reasons, this resistance of the brain to vaccinal phlegmasia is an established fact. Ledingham and Barratt, by injecting large doses of neurotesticular vaccine into the veins of rabbits, have produced local and visceral reactions; but the brain remained unaffected.

Such then was the knowledge obtained by observation and experiment until the recent work of Eckstein which opened a new horizon to experiment and pathology. Eckstein turned his attention not to rabbits, the ritual animals, but to monkeys. These had already been employed by other investigators but instead of using the usual channels of inoculation the failure of which to produce encephalitis was notorious, Eckstein adopted the intrathecal route In this way, he claims to have succeeded in producin a disseminated meningo-myeloencephalitis clinicall and histologically identical with human post-vaccin encephalitis. There was no failure, since of 1 monkeys injected with several varieties of lymp all fell ill, even after very small doses, whilst of thr animals injected with massive doses of lymph in the arteries none presented similar signs.

These results require to be confirmed, the more as they are in opposition to the present histologic evidence according to which the vaccine vir inoculated directly into the brain produces lesio which differ from those of post-vaccinal encephalit Can any inferences applicable to the human ca be drawn from these experiments. Have th resulted from the invasion of the cerebro-spi fluid by the virus? If so, it should be proved from sufficient series of cases systematically examined t in normal vaccination the virus is not detectable the cerebro-spinal fluid, but that it is to be fou in the vaccinations followed by bad results. (would then arrive at the following pathoge mechanism: the invasion of the brain is promo by the vaccine which, surmounting the vasc barrier, invades the fluid medium which surrou and protects the nervous centres. Why and how function of these protective barriers is deranged wo still remain to be explained.

Conclusions of Part I.

What has been said above shows that there weighty reasons to inculpate vaccinia itself as author of the encephalitic process; these reas nevertheless are not sufficiently strong to be gener convincing. It is repugnant to believe that operation whose innocence in this respect has shown by 100 years of world-wide experience, which every year continues to be performed by million without any ill-effect, should be capabl such wrong-doing. How, it is asked, can one impli the lymph which, in its country of origin, has n produced nervous troubles, but which, transpo to another country in which encephalitis exists, been followed by accidents? For instance, the vac imported from Denmark, where no case had observed, caused in Holland as much enceph as the native strains (Peter Holst[27]).

This extreme rarity and the caprices of incid make the idea of attributing the causation of encephalitis to the lymph repellent. Others turned to the invocation of dysergies of the virus have called in aid factors which bring the inf process into play—hyperergia; allergia; parallel

ctic failure—but without coming nearer the
ion of the problem. Nor have we advanced it
nvoking mutation of the virus, or individual
sive power.

e are certain that a virus is concerned. If
nal virus is not guilty, where is the other to be
l ?' This virus x remains unknown. It would be
which would engender the encephalitis in bivalent
biosis with the vaccinal. The vaccinal does no
than cause the occult virus to spring into patho-
activity, in the same way as the priming causes
explosion of the powder. A mysterious virus,
g and moving in a complete physiological silence,
revealing its morbigenic force when in catalytic
act with cow-pox.

check to this hypothesis, probable or not in pure
ry, was the absence of other forms of encephalitis
parable to the vaccinal. It was difficult to
rstand how a really encephalitogenic virus
l have no effect by itself and could only exert
nfluence when aided by vaccinia. This objection
recently been removed by the study of post-
tious encephalitis and acute spontaneous dis-
nated encephalitis. Here, then, is a further
ct of the problem to be considered and another
to its solution.

(*To be concluded.*)

A USEFUL CATALOGUE.

WE have received from Messrs. Mayer and Phelps
ir new catalogue of surgical instruments and
pliances. These are mostly made in a factory
hind the premises in New Cavendish-street, so that,
th few exceptions, all the articles in the catalogue
of British manufacture. The productions of the
m practically cover every medical or surgical
ergency, and it is noticeable in the catalogue that
great many of the instruments have been made, or
being made, according to particular specifications
m well-known practitioners. The catalogue is
efaced by some interesting and practical notes upon
value and limitation of stainless steel for surgical
struments.

NEW PREPARATIONS.

EPHEDROL (Messrs. Clay and Abraham, Ltd., Liverpool).—This preparation of ephedrine, the formula for which is: ephedrine 1·0, camphor 2·0, aromatic oil q.s., neutral oil add 100, is supplied in a bottle with a rounded nozzle from which the fluid is inhaled or sniffed. The physiological effects of ephedrine are similar to those of adrenalin, but the action is more prolonged. It enjoys good repute in the treatment of asthma, for the remedy of which it is said to have been employed for 1000 years in China, its home country. When applied to the congested nasal mucous membrane ephedrine reduces turgescence without causing local irritation.

UROSELECTAN B.—Messrs. Schering, Ltd., 3, Lloyd's-avenue, London, E.C., have sent us a sample of the preparation termed Uroselectan B, which is now frequently employed as a contrast agent for the radiographic visualisation of the kidneys and urethral tract by intravenous injection. Chemically it is a di-sodium salt of 3·5 di-iodo-4-pridoxyl-N-methyl-2·6-dicarboxylic acid and is supplied in ampoules of 20 c.cm. solution ready for use. At a meeting of the section of urology of the Royal Society of Medicine, held in March, 1931 (vide THE LANCET, April 4th, 1931, p. 757), Prof. A. von Lichtenberg, of Berlin, delivered an address on excretion urography, in which he reported upon the results obtained in the employment of several new intravenous contrast substances, and spoke of the decided advantages obtained through uroselectan B.

MERCOLLOID.—We have received from Messrs. Coates and Cooper, Ltd., 94, Clerkenwell-road, London, as agents for The Bio-Chemical Laboratories, Ltd., Locarno, Switzerland, samples of Mercolloid, a preparation of colloidal mercury sulphide for which a special spirochætal value is claimed; in the view of the manufacturers the drug is indicated in syphilitic and parasyphilitic affections of every kind. Its value in psoriasis is also stressed. The preparation is a colloidal mercury sulphide in finely dispersed pure suspension, made up in ampoules of 2 c.cm., each ampoule containing 0·010 g. colloidal mercury sulphide. Intramuscular injections are made daily, or at other time intervals as directed by the practitioner.

PERCAINE CIBA (Clayton Aniline Co., Ltd., 40, Southwark-street, London, S.E.).—A sample of this preparation, a 2 per cent. isotonic solution of percaine "ciba," is supplied in a 30 c.cm. bottle. Percaine, as we said in these columns on its introduction as a new local anæsthetic, should be a valuable adjunct to the agents available for producing local analgesia, and during the two years that have elapsed we have heard no reports of ill-effects from its employment. The solution of the strength now supplied has been specially introduced for surface anæsthesia of mucous membranes in oto-rhino-laryngological work, and may be applied by dabbing, painting, or as a spray. A recent article in the *British Medical Journal* (Nov. 28th, 1931, p. 986) by Mr. M. C. G. Israel, M.Sc., and Dr. A. D. Macdonald has confirmed the claims of the manufacturers that the solutions can be sterilised by heat without loss of strength; they find that sterile solutions are stable and retain full activity for at least several months. The minimal effective concentration of percaine for producing surface anæsthesia in the human subject was found to be about 1/40 of that of novocain. The preparation is intended for external use only by application to the mucous membrane.

INSTITUTIONAL TREATMENT OF ALCOHOLISM.

THE superintendent of the Bay Mount Home at Paignton classifies his cases for 1930 into three groups: patients who have become chronic alcoholics for no obvious psychological reason, but as a result of constantly drinking with friends and business associates; alcoholics who drink for some definite psychological reason (e.g., to relieve a phobia); and the true dypsomaniacs, who develop a periodical craving for alcohol which continues until the patient is saturated and then stops abruptly. The first class of case can be cured for certain in an institution if the patient wishes. Most of the cases in class II. are also curable, but need psychotherapy besides medicinal treatment. During the year the Bay Mount Home received 18 cases in class I., 12 cases in class II., and 2 cases in class III.; also 5 drug cases, 2 cases of obsessional neurosis, 2 of exhaustion neurosis, 3 of neurasthenia, and one ill-defined case of insomnia. The medical superintendent declares that every year that passes strengthens his opinion that almost any case of inebriety can be cured if the patient can and will give the time and make the effort necessary. Patients who have been treated successfully often return periodically for ten days or so to have tonic treatment, and this habit has proved very valuable to them.

STERILITY OF HANDS IN MIDWIFERY.

In the course of a paper read before the Edinburgh Obstetrical Society on Dec. 9th, Dr. Lachlan Grant reviewed the possible sources of infection in childbirth. In deliveries conducted in the home, he said, several basins, enamel or porcelain, are usually employed. These may be boiled, scrubbed out, or flamed with spirit. Thereafter, an unmeasured quantity of disinfectant is poured into an unmeasured quantity of water and the lotion is supposed to be ready for immediate use. The interior of the receptacles is rendered slightly more sterile by this means, but the difficulty is that the basins are very liable to contamination *anew* owing to the cleansing, swabbing, and rinsing. The completely sterile basin can only be produced by constantly subjecting it to steam heat or by keeping it in contact with a suitable chemical solution for adequate periods. If microbes are deposited in freshly prepared solutions of, for instance, perchloride or biniodide of mercury 1/1000, five to ten minutes must elapse before the solution is rendered sterile and quite safe for further use.

One of the most effective methods to adopt, both in the home and in institutions, is to employ some form of elevated water flushing apparatus. What is required is the same type of faucet as that used in operating theatres, so that contact with the unclean sides of the basin walls is avoided. The portable spray which Dr. Grant described consists of separate rubber joint attachments to both hot and cold lavatory-basin or bath-tap inlets. These are fixed by a screw and rubber join. The junction of the hot and cold rubber tubes is not far from the spray nozzle, and the combined spray is supported on a pedestal; by means of a non-return valve in the hot-water tube the temperature of the flowing spray is easily regulated. Where tap unions are found unsuitable, or where a portable spray is not at hand, it is necessary to find an appropriate substitute. The following apparatus, in Dr. Grant's opinion, is simple, safe, and efficient. A large irrigating jar or reservoir is elevated some six feet, supported on a stand or shelf. It has a draw-off tap at its lower end, and is fitted with a rubber tube to which is attached a small neat strong glass or nickel spray or jet. The spray is supported centrally over a wide-mouthed basin or bath some 20 in. in diameter and placed on a stool or chair at a height to avoid splashing. This bath receives the soiled fluids falling from the washed gloved skin or instrumental surfaces, and there is no possible reapplication of bacteria. Antiseptic solutions can be used, and the flow is available alongside the patient's bed—a great advantage. An electric portable immersion heater can at times be used to keep the temperature right. For large institutions it would be possible to have fixed electric heating unit reservoirs on trolleys which could be wheeled to any bedside.

Instead of an elaborate make of reservoir with a lift-up lid and special draw-off tube, Dr. Grant suggested that a simple syphon-action arrangement could be used in the homes of patients. The Rotunda douche is exceptionally suitable, the usual glass vaginal douche being withdrawn and a small glass spray taking its place. The jug or ewer reservoir is raised and fixed and the basin to hold the used solution is placed on a stool or chair. The spray hangs centrally over this basin. By means of two jugs or reservoirs, two Rotunda douches, and a glass Y-piece, with the spray nozzle attached to its lower end, one can make use of either sterile water or lotion as required. The same applies to the larger makes of reservoirs for hospital use. Dr. Grant urged that the washing, rewashing, and dipping of hands after contamination in a stationary aseptic or antiseptic solution in a basin is not to be compared with the action of the downward spray cleansing. Spray in larger reservoirs can be operated by a foot pedal. At present the flow is started and stopped by hand. To overcome the difficulty of the cleansed hand surfaces coming in contact with the spring clip or handle of the tap, he has prepared small sheets of sterilised paper encased in sterilised envelopes. Larger sheets of sterilised paper may be used for laying out instruments.

Appointments

Crisp, T., M.D., Ch.B. Edin., Medical Referee under the Workmen's Compensation Act for Chorley, Lancaster and Preston County Courts.

Edwards, Sybil O., M.B., Ch.B. Lond., D.P.H., Asst. M.O.H., Lowestoft and M.O. of Schools.

Howell, Nancy G., L.R.C.P. Lond., M.R.C.S., Asst. M.O.H., Acton.

The Home Secretary gives notice of a vacancy for a Medi Referee under the Workmen's Compensation Act, for t Districts of the Dewsbury and Leeds County Cou (Circuit No. 14). Applications should reach the Priv Secretary, Home Office, Whitehall, London, not later th Feb. 6th.

ADDRESSES AND ORIGINAL ARTICLES

THE ÆTIOLOGY OF CARCINOMA.*

J. J. M. SHAW, *M.C.*, M.D., F.R.C.S., F.R.S. EDIN.,
ISTANT SURGEON TO THE ROYAL INFIRMARY, EDINBURGH; LECTURER IN SURGERY AND ASSISTANT TO THE PROFESSOR OF SURGERY IN THE UNIVERSITY OF EDINBURGH.

THE field of cancer investigation is wide; the workers therein are many and of great diversity in training and outlook. The extent and many-ledness of the problem render its presentation a matter of considerable difficulty. This difficulty lies mainly in the comprehension and proper coördination of the vast amount of relevant information which is available and not, as is sometimes suggested, in the vastness of our ignorance of the nature of the process. Whichever view be held, it is advisable for each of us to formulate the question from time to time, "What do I understand by the term Cancer?" and to attempt to coördinate our ideas so that we may assess the value of new observations in the chain of causative factors. An effort in this direction is preferable to the attitude of awaiting the discovery from some source, as yet undiscerned, of a single and intimate ause of cancer, because it has become almost certain hat no such single proximate cause exists.

In traversing the wide range of fact and opinion which demand consideration, there is a choice of two methods. Either a narration may be given of a long series of observations, experiments, and theories, or an attempt may be made to weave these into some measure of sequence so that the gaps in our knowledge may be emphasised. At a time when cancer investigation has lately suffered the loss of Archibald Leitch, it may not be considered too presumptuous if an attempt is made, by choosing the second method, to follow his precept to place our facts in order.[1] I hope it may thus be possible to provide a thread on which the more important observations may be linked together and, in this form, be more easily understood and remembered.

Growth and Independence of the Cell.

We will regard carcinoma as the process of growth in cells which have either failed congenitally to come under those influences which determine cell function and form, or which, after being subject to such differentiating influences, have become independent of them owing, apparently, to a prolonged change in environment.

A definition of cancer as a disease would demand a different statement in which the tendency towards fatality in the host and the apparent anarchism of the carcinomatous cell group assume prominence. In a consideration of ætiology, however, it is desirable to put aside this "malignant" aspect of the question—i.e., the effect upon the host— and to postulate an essential "naturalness" in the process as a physiological response to the influences which act upon the cell. The possibility of lawlessness or vagarious action on the part of a living cell would at once render a discussion of causation entirely sterile. The ideas of "unnaturalness" and "lawlessness" have drifted into the study of the cancer problem by strained analogies with the conduct of beings endowed with the power of thought.

The neoplastic process is founded upon the potentiality for independence of all the cellular entities which, in their aggregation and sufficient coördination, give us a composite living body. The cell is primarily an individual and secondarily a citizen. The tissue culture slide, the persistence of cell life for several days after somatic death, the free grafting of tissues, the vitality of the spermatozoon, and the self-sufficiency of the ovum—all these proclaim a capacity for survival of cells in the disjoined state, either when specially prepared for separation as are the reproductive cells or when artificially separated as in the other instances. The capacity for growth in the living cell should not be regarded as a specialised function or as an alternative to other specialisations. The view of M. T. Burrows, that the cell may swing now to growth and now to other function according to the presence of a growth stimulant (archusia) in excess, or a work stimulant (ergusia), cannot be fully maintained. Cramer expresses the position clearly when he says:

> "The similarity between the process of growth and other manifestations of cell life suggests that growth should be looked upon simply as a property inherent in living protoplasm in the same sense as metabolism, contractility and irritability. This is by no means a new conception. It is emphasised again because the conclusions drawn by many recent workers on the growth problem frequently suggest or imply that growth is a property which can be added to or taken away from living protoplasm. Such expressions as cells 'losing' or 'acquiring' the power of growth suggest that cells contain or possess something which is absent from cells which are said to have 'ceased to grow,' and a similar conception is implied in the term 'growth-substance.'"[2]

Warburg expresses it thus: "The resting condition of adult tissue is only apparent; in reality it is a condition of equilibrium in which growth and decay counterbalance one another."[3] In Nicholson's words: "Excessive growth and therefore tumour formation is one of the physiological potencies of every healthy cell."[4]

DIFFERENTIATION.

We are prone to regard a specialisation of function and a corresponding differentiation of structural form as the natural condition of the cell, especially the epithelial one. Should these not rather be regarded as an imposition upon the individual for the communal welfare, entailing a sacrifice of its natural proclivity towards free growth and reproduction which are its essential properties? The living cell is a plastic and versatile entity which is capable of rapid reversion towards its true primitive form, as shown when the leash of control is removed in the urgencies of repair.

Differentiation is not manifest in the earliest stages of the developing embryo. It may disappear temporarily during the processes of repair. May it disappear finally if factors resembling those responsible for the proliferations of repair are allowed to act over a prolonged period of time so that an inveterate habit is established? Ewing states that inflammatory hyperplastic processes pass by insensible gradation into neoplastic growth according to our present analysis.[5]

The group of cells which is irresponsive to the differentiating influences is not extruded from the body. In their capacity for acquiring sustenance they may alter the metabolism of the host. As Carter Wood remarks: "The fact that cancer cells are a real independent life inside the body, just as much as the fœtus is, and perfectly adapted to the soil in which they grow, does not seem to be fully recognised."[6] Such a growth induces changes in the blood and other tissues of the host, and one of the chief difficulties in our present state of knowledge is to decide how far these manifestations are causal in nature and how far they are secondary or incidental. In a consideration of ætiology we must be careful that changes such as those observed in the blood which result from the presence of the independent growth are not described as factors which cause that independence until their exact interpretation is determined. A study of the blood and excretory changes in pregnancy yields valuable information and provides useful tests, but deductions in regard to fœtal origin have not been made from them. With full recognition of the value of their work, I shall refrain from discussing the observations of such workers as Shaw Mackenzie, Bendien, Haddow, Maisin, Pacetto, and many others who have studied the serological reactions, &c., in cases of established cancer.

---

* A post-graduate lecture delivered at Edinburgh.

Three Ways in which Carcinoma is Produced.

It has been indicated that the state of non-differentiation may be shown either by cells which have never reached maturity of structural form or by the descendants of cells which have been differentiated but which have been altered by some means so that differentiation has been modified or has disappeared. A recognition of this distinction is important and serves to prevent the stultification of discussion which occurs when the expositor of an extrinsic cause is assailed with the question, "What can your extrinsic cause have to do with, say, the renal blastoma of the infant?"

We may succeed in rendering the question less difficult if we describe three different methods of production of carcinoma, a grouping which has the additional advantage of bringing the various branches of experimental work into perspective with the human manifestations :—

(1) *Implantation*, in which a growing carcinoma is transferred from one host to another and continues to grow without apparent modification.

(2) *Continuing*, in which an embryonic cell group fails to come under the influence of the mechanism of differentiation and continues to grow in its natural primitive state and to reproduce in the manner of undifferentiated multicellular organisms. In this group the outstanding example is the renal blastoma or embryoma, which, often, cannot be accurately classified as carcinoma or sarcoma because the stage of differentiation into germinal layers has not been attained.

(3) *Conversion*, in which a single differentiated cell or cell group becomes altered under some change in environment so that its previous differentiation and specialisation disappear or become modified. In contrast to the processes of repair, this de-differentiation remains established.

IMPLANTATION.

The implantation group is interesting and demands a brief consideration, although we are dealing with cells which have undergone their carcinomatous mutation in another host. The corresponding experimental work, in which Russell, Woglom, and Murray have taken a prominent part, throws much light upon stroma reaction, species limitation, and individual refractoriness.

A true implantation consists of the transfer of living carcinomatous cells into a host in which they continue to thrive in situations in which epithelial tissue is not normally found. There are definite limitations to the capacity of the neoplastic cell in taking root in this way. The species limitation is extremely strict and in only one situation has a successful transplant been made from one species to another, when a mouse carcinoma was transferred to the brain of a rat. A few experimental tumours have become celebrat and are passed from one laboratory to another ow to their ready acceptance on implantation, wh places these tumours almost on the same plane the blood of a universal donor. When the destruct of an implant occurs, it is due to a fibrosis aid apparently, by the lymphocytic flood, in H. Wa phrase, which invariably appears. In a sub-effect excitation of the connective tissue, the stroma wh forms appears to be suborned to the service of the implant and, in place of a strangling and desiccating exterminant, it becomes an intermediary in the supply of such fluid as the carcinomatous cells require The influence of the fibrous barrier is shown in the arresting effect of an old pleuritic adhesion, occasionally in marked degree at the periphery of a melano-carcinoma and in other instances. The carcinoma cell may be reduced almost to the level of a spore, as shown by Heiman, of the Crocker Research Laboratory, when he implanted a very active carcinoma into the centre of a slow-growing transplantable fibroma of the rat.[7] In this fibrous prison the carcinoma survived but did not increase. On cutting up the composite tumour and liberating the contained cells, malignancy was rapidly demonstrated. Murray[8] has demonstrated that the resistance of the host is raised by the pre-existence of a cancerous implant which has been removed, and Lumsden[9] has claimed to raise resistance by some of the products of tumour autolysis. It is interesting to consider the possibility of a lowering of the anti-epithelial resistance in pregnancy which, as it permits the invasion of the trophoblast in the uterus, might also allow the acceleration of tumour growth in other parts, as has been frequently recorded. Although H. Ribbert's conception of tissue tension does not carry us far in relation to ætiology, it is of value as a description of connective tissue resistance against a carcinomatous invasion either by implant from another host or at the stage of irruption of the carcinoma cell from the epithelial zone.

This defence against epithelial invasion is, of course, evident with implants of normal epithelial tissue. If a small portion of a truly cut Thiersch graft be submerged into a connective tissue bed, it is invariably destroyed by fibrosis. It is only when a portion of "whole" skin, with its defensive barrier of corium, or an intact sebaceous or sudoriferous gland is disjoined and submerged that an implantation cyst is formed. In operative work the seeding of implants only occurs in conditions of malignancy, and the precautions against it, which Sampson Handley insists should be part of the ritual of every operation in cancerous cases, are never required in other work except the border states of independence such as the villous papilloma of the bladder.

In contrast to the fairly common observation of homo-transplantation by seeding, especially in breast work, it may well be understood that the transfer of a neoplasm from one human host to another will be as rare as its undesirability can make it.

Lecène and Lacassagne describe the case of a Frenc student who accidently inoculated his palm with tumou cells from a case of breast carcinoma by the breaking of syringe while he was in the act of withdrawing some exudat from the patient after operation. A neoplasm of the pal developed at the exact site of injury and a glandula metastasis made amputation of the arm necessary. O section the malignant nature of the growth was unquestionable.[10]

Parkes Weber showed recently to the Royal Society o Medicine the carcinomatous liver of an infant, aged 10 months, whose mother had died of melanotic carcinom three months after delivery. The mother had been operate upon, 18 months before delivery, for melanotic carcinom of the thigh. He described the case as the *first* reporte ansmission of a malignant neoplasm from mother to by intra-uterine inoculation.[11]

ll the recorded intentional attempts to transplant an tumour tissue have been unsuccessful. Some destroyed by fibrosis in the host. In the most nt attempt, which was reported to the German gical Congress in 1926 by Kurzahn, of Königsberg, graft failed to grow. This surgeon transplanted erous tissue from a breast into his own forearm. minations made at periods of six days, two weeks, six weeks showed only signs of absorption.[12] In arking that the result was quite different from e obtained in animals, he must have failed to ember that only a small proportion of spon- eous animal tumours can be successfully grafted d that the routine experimental work with a high portion of successful results is carried on with cultures of tumours of exceptional resistance to destructive agents in the host.

CONTINUING.

In amplifying the description of the group which have termed Continuing the renal tumour forms e chief basis, particularly in its brilliant description Nicholson in his work on "The Nature of Tumour ormation." The failure of differentiation in these mours is attributed, not to a fault in the cells, but a lack of the appropriate physiological stimulus to fferentiation, such as an aberration in development the capillaries.

As Nicholson affirms: "Cells will feed, grow, divide, d multiply for ever unless they are compelled by eir environment to make the effort to differentiate. his has been established by experimental methods in sue culture."[13] Some points from the summary of s analysis of the embryonic tumours of the kidney e :—

(1) They are congenital and represent enormously larged remnants of the renal blastoma of the embryo.

(2) They do not arise in cell rests but are cell rests.

(3) Their actively growing cells have always remained at early stage of embryonic development and have never oceeded beyond this stage of differentiation.

(4) These cells have retained the primitive physiological nction because they were prevented from undergoing the ocess of differentiation.

(5) The inhibiting influence is not an inherent fault in the lls but depends upon an anomaly of the environment to hich they were subjected at an early stage of their life story.

(6) There is evidence for the assumption that this anomaly of the nature of a defect of tissue correlation which may ave ceased to act long ago.

MacCarty, in a paper upon the Cancer Cell and Nature's Defence Mechanism, has described tissue ifferentiation in the human body as occurring in such way that it may be divided into three recognisable tages.[14] First, there is seen the establishment of the eneral alignment of the cells which is shown in the ormal arrangement of adult tissue, the cells themselves remaining undifferentiated; second, the establishment of cellular polarity; third, the establishment of the adult morphology of the cells. In the condition of no differentiation and in the first and second stages, the cells bear almost no resemblance to the adult form. Little is known of the active agents in this process of differentiation, whether it be nervous, vascular, or chemical, in so far as these are capable of separation, or whether a functional demand will evoke a stimulus to persistence and reproduction in a certain form on the principle by which Halsted has shown that a parathyroid graft will succeed where a deficiency of parathyroid secretion is present, whereas it will fail if introduced into a host with an adequate supply.[15]

What other tumours fall into this category of truly congenital and compass the ultimate destruction of the host through an early failure of his own differentiating capacity? The embryonal testicular tumours would probably furnish examples if more fully demonstrable. In the more rudimentary teratomatous groups which manifest themselves at an early age it is generally believed that the neoblastic tissue develops at the expense of other cell layers or types which had reached a slightly fuller differentiation. Ewing expresses the matter succinctly in regard to rate of growth:

> "Why one teratoma grows slowly and produces adult tissues while another develops rapidly and remains embryonal in type cannot readily be explained, and this variation may possibly call for a wide difference in the stage of development of the original cell. A more obvious factor is probably found in the influence of the blastomatous process which is usually added to the embryonic growth and converts the embryo into a true tumour. Beginning early, the blastoma may completely suppress the embryo or, if late, the embryo may reach the limit of its growth before the blastoma assumes serious proportions."[16]

It should be noted that Ewing adds something, the blastomatous process, to the embryonic growth. Nicholson appears to be reasonable in regarding the differentiation as the addition or superimposition. The growth of the differentiated tissue is slowed down, according to his view, and the blastoma represents unchecked growth.

The neuro-epithelioma and medullo-blastomata which usually appear about the age of ten years are ascribed to a residual, sequestrated group of cells which have persisted in undifferentiated form during a long lag period until some systemic influence, such as the action of an internal secretion or a fractional change in the pH content of the blood, leads to more rapid growth. Certain of the thyroid carcinomata and the hypernephroma group may be predetermined by a persistent undifferentiated deposit. One other group which must be included is the nævus cell carcinoma. In this melanoma the capacity for survival of an epithelial, or at least, in P. Masson's view, an ectodermal, cell in a connective tissue medium is a characteristic of the cell from the outset. It may wait for a long period before some form of trauma or chemical stimulus initiates the rapid proliferation of the frank carcinoma. Dawson believed that the fibrosis of the corium is the effective restraining agent throughout.[17]

It will be obvious that this Continuing group complies with the conception of Durante and Cohnheim of embryonal cell rests. Their views remain of value, although the extension of them to include all manifestations of the cancer process now receives very little support.

CONVERSION.

The Conversion group must be regarded as the most important. The Implantation group demands a place in a logical examination but the human examples are negligible in number. The Continuing group is larger but their nature practically precludes the possibility of experimental study, except upon the lines of genetics. Our hopes lie in a fuller undestanding of the Conversion group, and our reasonable expectation is that, with increasing knowledge, measures of prevention may reduce their incidence, as it has already done in some of the occupational examples of this type.

In the Conversion group the differentiated cell, or the germinal layer which is the less differentiated immediate antecedent of the fully adult type, is influenced by some change in environment to forsake its previous habit and morphology and to transmit the new characters through successive generations. From the standpoint of the host the process may rightly be regarded as a perversion. We desire, however, to maintain the physiology of the cell as the fundamental consideration, and we must assume that the modifications which occur are the inescapable results for a given cell of the influences which act upon it and so determine its conversion. The independence of the altered group of cells and their worthlessness to the general metabolism of the host are evidenced by the fact that their growth may reach its most exuberant stage when the host is reduced to the extreme of inanition.

General Factors in Conversion.

While it is desirable that the problem of cellular conversion should be regarded as a search for local influences, it should be stated that certain general factors are of importance in determining the degree of readiness by which the local changes are induced.

Heredity, in its racial and familial aspects, has an influence. The work of monumental patience and accuracy of Maud Slye would in itself confirm this view. It is evident that the same change in local environment may ultimately produce in one individual a carcinoma, whereas in others the result will not proceed beyond a local hyperplasia or papillomatosis. This is exemplified in the experimental application of carcinogenic substances such as gas-works tar. With a known tar and similar strains of mice the percentage of results can be estimated with considerable accuracy. It has been demonstrated that this varying degree of resistance is alterable by such factors as the presence or pre-existence of another carcinoma in the host. It happens also that the establishment of a carcinoma has the effect of raising the immunity of the host to such a degree that epithelial modifications which may be progressing towards malignancy are rapidly halted and may be cast off. The careful work of C. E. Dukes on the disappearance of all or a number of papillomata in the bowel and elsewhere is now fully confirmed. I have seen a similar change on the ears of this rabbit. On the establishment of a frank carcinoma at the edge of one ear a fairly rapid reduction in the number of the multiple keratinised papillomata took place before the animal succumbed.

The environmental factors to which the capacity of carcinogenesis has been ascribed are of such number and variety that it would not be profitable to attempt to enumerate them. Before proceeding to analyse the process of a chronic or constant mild irritation repair, this de-alirenupon which my thread is laid, I shall

THE BRONCHOSCOPE IN THE DIAGNOSIS OF PULMONARY DISEASE.

BY A. J. SCOTT PINCHIN, M.D., F.R.C.P.LOND.,
PHYSICIAN TO CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK; TO WEST LONDON HOSPITAL, AND TO HAMPSTEAD GENERAL HOSPITAL;

AND

H. V. MORLOCK, *M.C.*, M.D., M.R.C.P.LOND.,
ASSISTANT PHYSICIAN TO CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS; TO MILLER GENERAL HOSPITAL; AND TO HAMPSTEAD GENERAL HOSPITAL.

ACCURACY in diagnosis must always be the primar aim of any physician; for without a correct an limited diagnosis treatment cannot be scientificall applied.

The physician especially interested in diseases the chest can often arrive at an accurate diagnos quite speedily: by taking a careful clinical histor by making a complete examination of the orga of the thorax with his eyes, hands, and ears; examination of sputum macroscopically, mic scopically, and culturally; and by the intuiti process which comes mainly from the mental formed of a disease after seeing a large number cases. Only at this stage, and with the knowle gained before him, should the interpretation of shadows shown by the skiagram be undertak Yet in a certain proportion of cases, although possibilities in the differential diagnosis have b reduced in number by these examinations, there still some doubt as to the disease present, and a defi diagnosis may be of vital importance to the pati in point of view of treatment.

The same impasse, after clinical and radiolog examination has been completed, is met with diseases of other systems. In the intestinal urogenital tracts a more accurate diagnosis can o be arrived at by *visual* investigation, the sigmo scope, gastric camera, gastroscope, and cystos serving for these purposes; moreover there ca little doubt that it is more satisfactory to *see* the le than to postulate one by a process of elimina and deduction. Though the above-mentioned in ments have been used in their respective sp for many years, the bronchoscope, which was inve by Killian in 1898 and improved upon by Brü

1908, nearly twenty-five years ago, has been emely little used in the diagnosis of disease of the iratory tract. In this respect we have been iderably behind the Americans, who for several s have been describing it as a valuable adjunct ulmonary diagnosis and treatment. This failure se an instrument of so great value may have n due to the fact that up till recent years it has n in the hands of the laryngologist, whose modesty prevented him from advancing into the realms he chest physician; whilst the latter, on his side, been too shy to suggest that he might be surgeon ugh to examine the lungs of his patients.

Ve ourselves, having for some years been distressed he general inadequacy in this respect, considered dvisable to acquire the training necessary for the e use of this instrument in our work. Those of patients in whom diagnosis was in doubt, after rough investigation by other means, have been mined bronchoscopically, and form the smaller t of a series of 450 bronchoscopies carried out our clinic last year. The object of this paper o place on record the results of these investigations, d the conclusions formed therefrom.

In carrying out these investigations we have used pecially constructed bronchoscope with a telescopic achment, which gives a forward illumination nost equal to that obtained in the Haslinger strument. It has been constructed for us by . Schranz of the Genito-Urinary Company and a ll description will be published shortly after final provements have been made.

PULMONARY NEOPLASM.

A series of 25 cases were examined in this connexion d 21 of them were neoplastic. Bronchial carcinoma pears at the present time to be the most common rm of pulmonary neoplasm. The presumptive agnosis of this disease in the moderately advanced age is usually not difficult on consideration of the istory, clinical signs, and radiological examination; ut the assumption of malignancy cannot be *proved* ntil the disease has advanced to such a degree at secondary glands are available for section or etastatic deposits have occurred. In the moderately dvanced stage of the disease examination with the ronchoscope will usually show lesions which are eyond doubt, and allow of the removal of pieces f growth for section.

G. D., a man aged 50, was admitted twelve months ago ith a hæmoptysis. He had a scoliosis, with a boss which masked the X ray examination, which suggested fibrosis. Bronchoscopic examination showed a growth of the left ronchus and section showed this to be carcinoma. He had X ray therapy, and has recently died.

On the other hand, the bronchoscope may show that the lesion suspected as malignant is not so.

A. Y., a woman aged 60, had a breast removed for arcinoma seven years previously, and was sent to hospital with the diagnosis of secondary malignant disease on that side. The clinical signs were those of extensive fibrosis on that side, and the bronchoscope showed fibrosis only, with no evidence of malignancy.

J. D., male aged 45. The X ray diagnosis was neoplasm of the right root. He had a strongly positive Wassermann reaction, and bronchoscopy showed a fibrotic condition only, without evidence of malignancy.

If any successful treatment by surgery, radium, or X ray therapy can be evolved for the treatment of bronchial carcinoma, its success will depend on the earliest possible diagnosis; therefore one must be prepared to investigate with the bronchoscope all patients presenting any of the recognised early symptoms of the disease. One of the early symptoms may be hæmoptysis.

H. D., male aged 57. Three months before admission he was seen by a tuberculosis officer for hæmoptysis. Physical and radiological examinations were negative at this time. When seen as an out-patient he had definite signs at the right base, and bronchoscopy revealed a new growth which would probably have been equally obvious at the time of the initial hæmorrhage.

Another fairly early manifestation is collapse of a portion of lung distal to a bronchus occluded by growth. The accompanying signs and symptoms are probably the commonest early manifestation. They are generally an acute onset of pyrexia, pain, and cough, and are usually mistaken for pneumonia. After a somewhat prolonged course of four to five weeks, the symptoms abate and the patient feels better; nevertheless, the cough and physical signs persist.

H. N., male aged 44. Eight weeks before he came under our care he was admitted to a general hospital as pneumonia. After six weeks his condition improved, he became afebrile, and was discharged. Two weeks later he attended as an out-patient, when signs of collapse at the right base were confirmed by radiography. Bronchoscopic examination showed a carcinoma of the bronchus, which was confirmed by section.

L. G., male aged 50. Eight months before admission had "influenzal" pneumonia, and was treated at home for six weeks. Has had chronic cough and has never been well since. On admission he showed collapse at the right base, confirmed by radiography. Bronchoscopic examination showed carcinoma of the bronchus, and this was confirmed by section.

In both these cases bronchoscopic examination at the time of the "pneumonia" would have rendered diagnosis possible.

If the blockage in the bronchus is only partial, suppuration commonly occurs behind the obstruction, and the signs and symptoms are thus identical with those of lung abscess, and diagnosis can only be made by bronchoscopic examination.

W. N., male aged 55. On admission he had cough, pyrexia, and a small amount of purulent sputum. There were signs of consolidation and collapse of the right upper lobe. The skiagram suggested collapse, and showed no definite evidence of new growth. Bronchoscopy showed a new growth occluding the right upper lobe bronchus.

Less common are those cases presenting signs of pulmonary fibrosis, with or without bronchiectasis, and which have a prolonged course, often two or three years.

L. D., male aged 58, attended the out-patient department for two years with signs of pulmonary fibrosis at the left base with marked clubbing of fingers. During the two years there was no change in his condition, and a skiagram confirmed the presence of fibrosis. The patient was admitted for further investigation. Bronchoscopic examination showed a growth in the main stem bronchus just before the middle lobe bronchus, which was confirmed by section.

We wish to lay stress on the difficulty in getting these patients in the early stage of the growth. The patient in the earliest stages is perfectly well; hæmoptysis is not a *very* early symptom, and implies that the growth has ulcerated, and that it is highly probable that there is extension into the lung. Collapse also does not take place until the growth fills, or nearly fills, the bronchus. X rays show nothing until the lung has collapsed, and, even combined with lipiodol examination, will show nothing in the early stages before a considerable amount of occlusion has occurred.

It is essential that these cases be suspected earlier, at a stage when the growth is little more than a "wart" in the bronchus. Any middle-aged person, who has not been subject to coughs, and who develops a chronic cough, should be asked particularly if he feels any sensation of sticky mucus constantly in one place in the bronchus, if he has had any wheeze or rhonchus in one spot in the lung, which can be confirmed by stethoscope if present. If there is any constancy bronchoscopy is indicated. It is a procedure, which, in skilled hands, is devoid of risk and is no more unpleasant to the patient than a tooth extraction under local anæsthesia. By this means only will it be possible to get the disease in that stage when it is amenable to treatment by radium.

We have recently had a case in whom a growth had infiltrated from the bronchus to the extent only of a small walnut, and yet a secondary was present in the adrenal the size of a small orange.

PULMONARY SUPPURATION.

The diagnosis of pulmonary suppuration in its wider sense can usually be made on the history, physical examination, and the presence of purulent and often foul sputum. In the differential diagnosis of the cause and type of suppuration (e.g., pneumonitis, lung abscess, bronchiectasis, new growth or foreign body) bronchoscopy is of the greatest value, and we, with others, believe it to be an essential investigation in these cases The following synopses of case reports serve to bring out various points showing the value of bronchoscopic investigations in this class of case.

G. G., male aged 46. Sent from India for treatment of cough and foul sputum from which he had suffered for years. Physical examination revealed bronchitic signs, least marked at bases, and clubbed fingers. Skiagram nil. Lipiodol: widening of trachea. Sputum 12 oz. Bronchoscopy shows large bronchi generally and uniformly dilated, mucous membrane greyish and weeping pus. No evidence of bronchiectasis or abscess. The patient died later of pyæmia and autopsy confirmed findings. The case was one of purulent bronchitis.

C. G., male aged 16. Four months' swinging temperature, pain in right chest, cough and trace of sputum. Physical examination revealed consolidation at right base and clubbed fingers. Lipiodol was no help. We were asked by our colleague, Dr. Goodman Levy, to examine the boy with the bronchoscope. This examination showed that the external division of the right lower lobe bronchus was inflamed; it was dilated, a drainage tube passed and 2 oz. of thick pus was evacuated. A broncho-pneumogram confirmed the presence of an abscess cavity. The temperature fell, and after a few more treatments the patient was cured, and remains well.

In this case, for four months the diagnosis had been at fault owing to the fact that the bronchus of drainage was occluded. It is unusual for the diagnosis of pulmonary suppuration to remain so long in doubt.

J. R., a woman aged 35, after tonsillectomy developed a cough and fœtid sputum. She was seen by a chest physician, who diagnosed an abscess of the right lung. No special treatment was carried out, and for a year the patient went steadily downhill, with great loss of weight, sputum becoming more foul and more copious. Several skiagrams showed no definite lesion. Lipiodol revealed no abscess cavity. Bronchoscope showed pus coming from the bronchus supplying the upper part of the left lower lobe. Broncho-pneumogram showed the abscess cavity. On bronchoscopic drainage the patient is now well.

In this case there was no doubt as to the suppuration, but the exact nature of the lesion was not known until bronchoscopy was carried out, with the result that for a whole year the patient got steadily worse. Another point is brought out in connexion with this patient, and that is the value of defining the exact locality of an abscess by means of lipiodol placed down the bronchus of drainage under direct observation with the bronchoscope. In the ordinary case a much better lipiodol picture of the bronchial tree is obtained by the usual method of injection—e.g., crico-thyroid route, the oral method or the nasal catheter method, which last has incidentally been in use for several years on the continent. On the other hand, in a lung abscess the lipiodol given by [illegible] methods fails to enter the abscess cavity, [illegible] because the bronchus of drainage is obstructed [illegible] turgescent mucous membrane or because the [illegible] is full of pus.

By means of the bronchoscope the bronchus of drainage is dilated, the pus aspirated, and the [illegible] delineated with lipiodol.

The exact localisation is of the greatest [illegible] if the abscess subsequently requires treatment [illegible] surgical interference. Chevalier Jackson has [illegible] years maintained that all cases of pulmonary suppuration should be bronchoscoped because he believ[illegible] that a large number were due to foreign body. [illegible] may be a common cause in America, but we have [illegible] found it so in this country.

M. G., female aged 47. Tooth extraction four months before investigation. Pyrexia, cough, and purulent sputum with clubbed fingers, and signs of consolidation at right axilla. Skiagram confirmed consolidation. Bronchoscopy showed right middle lobe inflamed and pus pouring out. Aspiration was followed by coughing up a piece of tooth. Healed by bronchoscopic treatment.

A. H., female aged 49. Hæmoptysis, cough and pyrexia four weeks. Sputum offensive two weeks. Physical signs: mitral stenosis and consolidation of right base behind. X rays showed indefinite shadow at right base. Sputum was bile-stained. Diagnosis was liver abscess ruptured into bronchus. On bronchoscopic examination hydatid daughter cysts were found in the bronchi. Cure of hydatid.

As we have previously pointed out in this paper, when a new growth has occluded a bronchus, and produced pulmonary suppuration, a diagnosis is made of suppuration, and the underlying neoplasm is missed. The only method of determining the true nature of the lesion is bronchoscopy.

In general the differentiation between lung abscess and bronchiectasis can be made on *history*, physical signs, and lipiodol examination. None the less in the investigation of a case of bronchiectasis the bronchoscope is of value. In the first place a new growth of foreign body can be excluded as the cause, and further the number of lobes involved can be ascertained as may the extent of dilatation of the main bronchus.

There is a type of bronchiectasis occurring in children and young adults in whom, whilst the physical signs are extensive, the sputum is small in amount or absent. The skiagram shows a cystic type of bronchiectasis. Bronchoscopy shows normal-sized main bronchi, whose mucous membrane is smooth and healthy, and, branching from the bronchi, numerous smaller bronchi not usually seen. This type we have suspected as being of congenital origin, allied to the cystic lung.

M. K., a thin pale girl aged 11, who has always led a normal life. The school doctor found signs in the chest and sent her to the tuberculosis officer, who transferred her to us. Slight cough, little sputum (not foul), and fibrotic signs over the whole of the left chest. Skiagram, with lipiodol, showed a cystic like condition. Bronchoscopy shows the main stem bronchi healthy, many small adventitious bronchi arising from the main stem. Artificial pneumothorax and thoracoscopy confirmed the evidence in favour of congenital origin.

In some cases of pulmonary suppuration, by obtaining the pus direct from the depth of the abscess, a pure specimen may be obtained for microscopical and bacteriological examination; spirochætes or other organisms not found in the sputum may be found, and intravenous novarsenobillon be given or a vaccine prepared, as the case may be.

Although the bronchoscope is of value in the diagnosis and localisation of pulmonary suppuration,

ncipal use in this disease is in the treatment of it.
not our intention in this paper to discuss its
a therapeutic method, for we propose to deal
his aspect later.

OTHER DISEASES.

ot uncommon diagnostic problem arises in cases
noptysis when clinical and radiographic examina-
give no evidence of disease. In the young
t tuberculosis is suspected, and in the middle-
or older neoplasm. A lipiodol examination,
have reported previously, may show an unsus-
l dry hæmorrhagic bronchiectasis, and should
ore always be done. A bronchoscopic examina-
hould also be made before resting content with
certain diagnosis.

previously stated, an early carcinoma may be
, whilst in young patients a swab taken from
ronchial mucous membrane and examined for
le bacilli may give a positive finding which
not otherwise have been obtained. Some
tion or a vascular area may be seen from which
æmorrhage has arisen, as the following case
ates.

., male aged 20. For three years repeated hæmoptyses.
l condition excellent. Physical signs and skiagram
re. Lipiodol negative. Bronchoscopy shows a cres-
vascular septum opposite the right middle lobe
us. This was cauterised with silver nitrate. There
en no further bleeding during the last nine months.

example of the value of a swab.

L., female aged 21. Cough and wasting some months.
al signs of infiltration at left base. Skiagram shows a
r in this region. No sputum. Fæces negative for
everal times. Bronchial swab T.B. present.

neoplasm involving the upper lobe bronchus
ncommonly activates an old tuberculous lesion,
are found in the sputum, and the diagnosis is
med. We have had several cases of this type
e doing our own bronchoscopy. Bronchoscopy
s of the diagnosis being cleared.

have found the examination of value in many
cases which do not come in the above group.
ollowing are examples :—

B., male aged 50. Cough, pain, and dyspnœa.
al examination suggested dilated aorta. Radiography
ned and showed a lesion of the right root, indefinite
agnosis. Wassermann reaction positive. Broncho-
showed mucous membrane of the right bronchus and
ons pallid. Plaster-of-Paris appearance very suggestive
cific infiltration and fibrosis.

F., male aged 56, showed all the signs of mediastinal
r. Radiological examination could not exclude
sm. Wassermann reaction negative. Bronchoscopy
d bronchial carcinoma.

CONCLUSION.

our opinion bronchoscopic examination is a
valuable additional method in the investigation
ulmonary disease. In some groups, neoplasm
suppurative condition, it is essential. It is a
od which does not disturb the patient unduly,
in experienced hands is quite safe. In some
bronchoscopies performed under local anæsthesia
e than one-third of which have been done on
patients, who have gone home two to three hours
the operation) we have never seen any ill-effects
not had a complaint from a patient. In those
nts who come regularly for treatment in suppura-
conditions the reverse is the case; their readiness
ubmit to repeated drainage raised our suspicion
the cocaine spray was the attraction, but the
titution of percaine for cocaine failed to diminish
desire for treatment.

EFFECT OF BRAIN DIET IN SUBACUTE COMBINED DEGENERATION OF THE CORD.*

BY C. C. UNGLEY, M.D. DURH., M.R.C.P. LOND.,

ROCKEFELLER MEDICAL RESEARCH FELLOW; RESEARCH FELLOW IN MEDICINE, HARVARD MEDICAL SCHOOL, AND MASSACHUSETTS GENERAL HOSPITAL, BOSTON, MASS.

THE reasons which led to the trial of brain diet have been described in a previous communication,[1] in which the potency of brain for blood regeneration in pernicious anæmia, as measured by the increase of reticulocytes and red blood-cells in four cases, was shown to be about one-third that of liver. The present paper describes an attempt to estimate the potency of brain relative to that of liver, with regard to their respective effects upon the neurological symptoms of pernicious anæmia. It was decided to use, whenever possible, patients whose neurological condition had failed to improve on liver pulp derived from 240 to 480 g. of raw liver daily, or on similar amounts of cooked liver. In a large series of cases of subacute combined degeneration of the cord at the Massachusetts General Hospital,[2] the Boston City Hospital, and the Royal Victoria Infirmary, Newcastle-upon-Tyne,[3] it was possible to find only a relatively small number of such instances. Of the nine cases described here, seven were of this type.

Method.—The brains of freshly killed oxen were used whenever obtainable. At other times frozen brain was used. After cleaning and passing through a meat grinder, 480 g. of the ground material were administered daily in three or four divided doses in the form of a purée with orange juice. This mixture makes a drink of more or less fluid consistency, which is taken usually without difficulty. The patients were confined to bed as little as possible, and, although they were encouraged to walk, no re-educational exercises were instituted.

CASE RECORDS.

Nine cases have been treated with whole brain for from two to six months. Six improved and three cases failed to show improvement.

CASE 1.—A man, aged 50, had subacute combined degeneration of the cord, with signs of gross involvement of posterior and lateral columns. Neurological symptoms were of fourteen months' duration. Symptoms referable to anæmia had been present for three months before the neurological manifestations commenced. At first liver therapy had been irregular and inadequate. For the last five weeks, however, he had taken daily "domestic" extract[4] derived from 240 g. of liver, and for eight weeks before that commercial extracts derived from approximately 600 g. of liver together with 240 g. of raw liver pulp. His general condition greatly improved with disappearance of the anæmia, but without as yet any improvement in the neurological symptoms.

At the *commencement of brain diet* he was unable to stand alone, and required the help of two persons to walk even a few steps. He was unable to dress or undress himself or to write. Numbness and tingling involved the extremities, reaching to the elbows and to the knees. Red blood-cells numbered 4·53 millions per c.mm. The upper limbs showed diminished power with hyper-active deep reflexes, and Wartenberg's thumb sign[5] was positive bilaterally. Gross astereognosis was present with inability to recognise any except large objects. There was considerable loss of power in the lower limbs, with gross incoördination, absence of joint-position sense in the toes, and absence of vibration sense (C,128) below the knees. The knee- and ankle-jerks or rhonchus in one spot in the lung, which can be confirmed by stethoscope if present. If there is any constancy bronchoscopy is indicated. It is a procedure, which, in skilled hands, is devoid of risk and is no more unpleasant to the patient than a tooth extraction under local anæsthesia. By this means only will it be possible to get the disease in that stage when it is amenable to treatment by radium.

---

* A paper read before the fifty-seventh annual meeting of the American Neu . . . Boston, 1931. From the Medical and . . . sachusetts General Hospital, and the . . . of the Harvard Medical School; Bosto . . . Royal Victoria Infirmary, Newcastle-on-Tyne.

We have recently had a case in whom a growth had infiltrated from the bronchus to the extent only of a small walnut, and yet a secondary was present in the adrenal the size of a small orange.

PULMONARY SUPPURATION.

The diagnosis of pulmonary suppuration in its wider sense can usually be made on the history, physical examination, and the presence of purulent and often foul sputum. In the differential diagnosis of the cause and type of suppuration (e.g., pneumonitis, lung abscess, bronchiectasis, new growth or foreign body) bronchoscopy is of the greatest value, and we, with others, believe it to be an essential investigation in these cases. The following synopses of case reports serve to bring out various points showing the value of bronchoscopic investigations in this class of case.

G. G., male aged 46. Sent from India for treatment of cough and foul sputum from which he had suffered for years. Physical examination revealed bronchitic signs, least marked at bases, and clubbed fingers. Skiagram nil. Lipiodol: widening of trachea. Sputum 12 oz. Bronchoscopy shows large bronchi generally and uniformly dilated, mucous membrane greyish and weeping pus. No evidence of bronchiectasis or abscess. The patient died later of pyæmia and autopsy confirmed findings. The case was one of purulent bronchitis.

C. G., male aged 16. Four months' swinging temperature, pain in right chest, cough and trace of sputum. Physical examination revealed consolidation at right base and clubbed fingers. Lipiodol was no help. We were asked by our colleague, Dr. Goodman Levy, to examine the boy with the bronchoscope. This examination showed that the external division of the right lower lobe bronchus was inflamed; it was dilated, a drainage tube passed and 2 oz. of thick pus was evacuated. A broncho-pneumogram confirmed the presence of an abscess cavity. The temperature fell, and after a few more treatments the patient was cured, and remains well.

In this case, for four months the diagnosis had been at fault owing to the fact that the bronchus of drainage was occluded. It is unusual for the diagnosis of pulmonary suppuration to remain so long in doubt.

J. R., a woman aged 35, after tonsillectomy developed a cough and fœtid sputum. She was seen by a chest physician, who diagnosed an abscess of the right lung. No special treatment was carried out, and for a year the patient went steadily downhill, with great loss of weight, sputum becoming more foul and more copious. Several skiagrams showed no definite lesion. Lipiodol revealed no abscess cavity. Bronchoscope showed pus coming from the bronchus supplying the upper part of the left lower lobe. Broncho-pneumogram showed the abscess cavity. On bronchoscopic drainage the patient is now well.

In this case there was no doubt as to the suppuration, but the exact nature of the lesion was not known until bronchoscopy was carried out, with the result that for a whole year the patient got steadily worse. the Another point is brought out in connexion with organism, patient, and that is the value of defining the power locality of an abscess by means of lipi in which the down the bronchus of drainage under di few years ago tion with the bronchoscope. In t specific filter-pa much better lipiodol picture of in ta conjunctivis obtained by the usual met is extreme exact crico-thyroid route, the o successful odol placed catheter method, which last direct observa- use for several years on the ordinary case a

hand, in a lung abscess the lipiodol given by these methods fails to enter the abscess cavity, either because the bronchus of drainage is obstructed by turgescent mucous membrane or because the cavity is full of pus.

By means of the bronchoscope the bronchus of drainage is dilated, the pus aspirated, and the cavity delineated with lipiodol.

The exact localisation is of the greatest importance if the abscess subsequently requires treatment by surgical interference. Chevalier Jackson has for years maintained that all cases of pulmonary suppuration should be bronchoscoped because he believed that a large number were due to foreign body. This may be a common cause in America, but we have not found it so in this country.

M. G., female aged 47. Tooth extraction four months before investigation. Pyrexia, cough, and purulent sputum, with clubbed fingers, and signs of consolidation at right axilla. Skiagram confirmed consolidation. Bronchoscopy showed *right middle lobe* inflamed and pus pouring out. Aspiration was followed by coughing up a piece of tooth. Healed by bronchoscopic treatment.

A. H., female aged 49. Hæmoptysis, cough and pyrexia four weeks. Sputum offensive two weeks. Physical signs: mitral stenosis and consolidation of right base behind. X rays showed indefinite shadow at right base. Sputum was bile-stained. Diagnosis was liver abscess ruptured into bronchus. On bronchoscopic examination hydatid daughter cysts were found in the bronchi. Cure of hydatid.

As we have previously pointed out in this paper, when a new growth has occluded a bronchus, and produced pulmonary suppuration, a diagnosis is made of suppuration, and the underlying neoplasm is missed. The only method of determining the true nature of the lesion is bronchoscopy.

In general the differentiation between lung abscess and bronchiectasis can be made on history, physical signs, and lipiodol examination. None the less in the investigation of a case of bronchiectasis the bronchoscope is of value. In the first place a new growth of foreign body can be excluded as the cause, and further the number of lobes involved can be ascertained as may the extent of dilatation of the main bronchus.

There is a type of bronchiectasis occurring in children and young adults in whom, whilst the physical signs are extensive, the sputum is small in amount or absent. The skiagram shows a cystic type of bronchiectasis. Bronchoscopy shows normal-sized main bronchi, whose mucous membrane is smooth and healthy, and, branching from the bronchi, numerous smaller bronchi not usually seen. This type we have suspected as being of congenital origin, allied to the cystic lung.

M. K., a thin pale girl aged 11, who has always led a normal life. The school doctor found signs in the chest and sent her to the tuberculosis officer, who transferred her to us. Slight cough, little sputum (not foul), and fibrotic signs over the whole of the left chest. Skiagram, with *lipiodol, showed a cystic like condition.* Bronchoscopy shows the main stem bronchi healthy, many small adventitious bronchi arising from the main stem. Artificial pneumothorax and thoracoscopy confirmed the evidence in favour of congenital

diseases of other origin.

urogenital tracts a pulmonary suppuration, by be arrived at by *visu* from the depth of the abscess, scope, gastric camera, obtained for microscopical for these purpo mination; spirochætes or it is mor in the sputum may be one arsenobillon be given or a Though se may be.

In some cases of obtaining the pus direct a pure specimen may *be* used and bacteriological exam bronchoscope is of value in the other organisms not found and in pulmonary suppuration, intravenous now arked in degree, and involved the legs up to the nd each arm to a level well above the elbows. There arked pyorrhœa. The radial arteries were grossly ed, calcified, and tortuous. The cranial nerves ormal except for slight nystagmoid movements. pper limbs showed increased deep reflexes with e Hoffmann, Wartenberg's, and "paradoxical flexor-r" reflexes on the right side. In the lower limbs as some loss of power, and marked incoördination; ense was lost in the toes and ankles, and vibration was absent up to the hips. The knee- and ankle- were exaggerated and the plantar reflexes were sor" in type on stimulation of either outer or inner f the feet. Liver therapy was discontinued, and of raw ox brain was given daily.

e *end of six weeks* the red cell count was 4·5 millions nm. He was able to walk well, resting his hands arm-chair which he pushed before him. Numbness gling had diminished to the level of the wrists, and knees.

he *end of eight weeks* he was able to walk with a stick, en to manage a few steps without it.

he *end of ten weeks* the red blood-cells numbered llions per c.mm. He was now able to walk alone the ward without using the stick. Coördination of gs was very much improved, and there was some of joint sense in the toes. Spasticity was less, and ep reflexes less active. Some loss of weight had ed, but not enough in itself to account for the red gait.

ract No. 343 (N.N.R.) derived from 400 g. of liver w given daily in addition to the brain, but, in spite , the red cell count diminished further to 2·8 millions gh the neurological improvement was maintained. s point brain diet was discontinued and liver extract 3 (N.N.R.) derived from 1000 g. of liver was substituted. ed cells slowly increased to 3·4 millions per c.mm. riod of thirty days, at the end of which time resource ad to liver therapy by the intramuscular route.[7] aily injection of liver extract derived from 10 g. of for thirty-two days was accompanied by a further increase of red blood cells to 3·85 millions per c.mm., here was some further increase in strength.

is case showed rapid neurological improvement rain after failing to respond to similar quan- of liver. It is interesting, moreover, that the ovement took place despite the falling red blood- ount. The slowness of the subsequent hæmo- ic response to liver extract by mouth and also terally seems to indicate that this patient was considerable extent "refractory," and it can be ly understood why the red blood-cell count fell g the period of administration of brain. The of Beebe and Lewis[8] suggests that larger amounts tent material are required to maintain the red d-cell level in elderly than in young patients, cially if arterio-sclerosis is present.

e following two cases showed slighter degrees of ovement.

SE 5.—A widow, aged 59, had shown only slight ovement in gait, and no improvement in paræsthesiæ g treatment with 240 g. of raw liver daily for a year, with varying amounts of liver and liver extract before . Ox brain, 480 g. was given daily together with liver act No. 343 (N.N.R.) derived from 100 g. of liver, h was added in an endeavour to prevent a relapse of anæmia.

the commencement of brain treatment numbness and ing were particularly marked. Moreover, light touch e distribution of the paræsthesiæ evoked such intense widespread pain that thalamic involvement was ected. After seven weeks the numbness and tingling decreased very markedly, the hyperæsthesia of the ds is no longer evident, and there has been slight further ovement in her ability to walk. During this time the ell count fell gradually from 4·9 to 4·25 millions per c.mm.

SE 6.—A coal-miner, aged 59, had shown little or no ological improvement with about 1400 g. of cooked r per week for a year. While taking 240 g. of cooked n daily (i.e., three and one-half pounds a week) there almost complete cessation of flexor spasms of the legs, ch, accompanied by arching of the spine, had caused considerable discomfort. Paræsthesiæ improved in ree but not in extent, and his ability to walk was somet increased.

In three cases (Nos. 7, 8, and 9) the administration of 480 g. of raw ox brain daily produced no neurological benefit in a period of four months.

Case 7 was a married woman, aged 60, whose neurological symptoms had previously failed to respond over several years to relatively small amounts of liver and liver extract, including 240 g. of raw liver daily for five months.

Case 8.—A man, aged 63, was an advanced bedridden case with complete paraplegia in flexion and incontinence of urine, together with bed sores and urinary infection. He became worse, even though for four months liver extract derived from 600 g. of liver was given daily in addition to the brain.

Case 9.—A man, aged 46, had relatively slight neurological involvement but failed to benefit from brain diet even when combined with liver extract derived from 400 g. of liver and with thyroid medication.

ANALYSIS OF THE EFFECTS OF BRAIN DIET IN THE SIX IMPROVED CASES.

Five of these cases received daily 480 g. of raw ox brain, and the other received 240 g. of cooked brain. Case 5, noted above as having shown improvement of lesser degree, received daily, in addition to the brain, liver extract No. 343 (N.N.R.) derived from 100 g. of liver. With this exception, the neurological improvement occurred while brain diet alone was taken.

Of the six cases, four showed marked improvement, and in two the improvement was slight. The four which improved most were advanced cases which had previously failed to respond to from 240 to 700 g. of liver daily, the average daily amount being about 440 g. In two of them the liver dosage had been as much as 480 g. daily for six and seven months respectively.

Nervous System.—With brain diet four of the six cases showed distinct neurological improvement which was manifest within eight weeks. Formerly bedridden, they regained their ability to stand alone, and two became able to walk unaided; the other two could walk with the assistance of crutches or by holding furniture. Incoördination and ataxia greatly improved, and numbness and tingling decreased in extent and in intensity. Astereognosis, present in two cases, showed striking improvement in one instance and moderate improvement in the other. Vision improved in two instances and in one case there was, in addition, a notable improvement in memory. Sphincter disturbances, comprising difficulty and urgency of micturition, which were present in three cases, cleared up completely in one patient, and improved in another. The deep reflexes of the lower limbs, which had been exaggerated in two cases, became less active, coincident with a decrease in spasticity. The "extensor" plantar reflexes showed no significant alteration. Vibration sense (C, 128) returned in the lower extremities in one instance; in another patient, vibration sense returned to the bones of the hand and forearm although remaining absent in the legs. The latter case showed, in addition, a return of joint sense in the fingers. Three other cases showed some return of joint sense in the toes. One of the markedly improved cases subsequently relapsed following an upper respiratory infection, both the blood and the neurological symptoms being affected.

The improvement of lesser degree which occurred in two of the six cases has been described.

The Blood.—During the period of brain diet, and coincident with neurological improvement, the red cell count gradually diminished in four instances as follows: from 4·4 to 4·2, 4·0 to 3·2, 4·8 to 3·7, and 4·9 to 4·3 millions per c.mm. In each case it was considered desirable, after periods varying from two to six months, to add or substitute liver or liver extract in order to combat anæmia. The significance of these findings is discussed below.

were exaggerated, and the plantar reflexes extensor in type. He was instructed to discontinue liver and to take one pound (480 g.) of fresh raw ox brain with orange juice, daily.

After five weeks the red cell count was 4·4 millions per c.mm. He was now able to stand alone and to walk without help, occasionally steadying himself by holding on to objects as he passed them. He could undress without aid, though he still needed help to dress. Paræsthesiæ had diminished greatly in degree, and no longer interfered with sleep. The level of numbness had decreased to the wrist and ankle. Stereognosis had greatly improved, so that he could recognise any test object. There was an increase in the power of the upper and lower limbs, and coördination of the legs had considerably improved.

After fourteen weeks the red cell level was 4·2 millions per c.mm. He could now walk alone without holding objects to steady himself, and could run for a short way with help. Except for assistance with very small buttons he was able to dress himself, and he recommenced to shave himself, using a "straight" razor. There was greater strength in the limbs, and coördination of the legs was only slightly impaired. There was slight improvement in joint sense, but no return of vibration sense, nor any change in the plantar reflexes. He continued to improve, so that he was able to climb stairs without difficulty. Six months from the commencement of brain diet he suffered a gastro-intestinal upset in which nausea and vomiting occurred with a feeling of general weakness. Two weeks later the red cell count had fallen to 3·5 millions per c.mm. and paræsthesiæ increased, but there was no increase in incoördination. Liver therapy was temporarily substituted to combat the anæmia. A few days later the feeling of weakness had practically disappeared, and it was clear that the neurological improvement which had developed during the period of brain treatment had not been seriously affected by the relapse of the anæmia.

The neurological improvement in this case was rapid and occurred in spite of a gradually falling red blood-cell count.

CASE 2.—A farm hand, aged 39, entered the hospital with subacute combined degeneration of the cord of two years' duration. For seventeen months he had taken about 960 g. of cooked liver a week, with liver extract No. 343 (N.N.R.) derived from 300 g. of liver daily. For the past six weeks he had been given from 480 to 700 g. by weight of raw liver daily while in hospital. Symptoms referable to anæmia had disappeared, and his general condition was excellent, but the neurological symptoms had become worse even during the last six weeks.

At the *commencement of brain diet* the red blood-cells numbered 4·2 millions per c.mm. He was unable to stand or to walk even with the assistance of two persons. Memory was somewhat impaired, and his vision was defective. He was troubled with urgency of micturition. Numbness and tingling were present in the finger-tips, and in the legs up to the calf. The cranial nerves showed no evidence of abnormality except for slight nystagmoid movements. The upper limbs showed slight incoördination and diminished vibration sense; the deep reflexes were increased, with positive Hoffmann's and Wartenberg's reflexes on the right side. There was marked loss of power in the lower limbs with gross incoördination on the heel-knee test and almost complete loss of sense of position. Joint sense was absent in the great toes and vibration sense (C,128) absent below the twelfth dorsal vertebra. The knee- and ankle-jerks were absent and the plantar reflexes showed an "extensor" response on stimulation of either the inner or the outer sides of the sole; Oppenheim's sign was positive. The basal metabolic rate was minus 13 per cent.

Liver treatment was discontinued, and 480 g. by weight of raw ox brain pulp were administered daily.

After seven weeks the red cell count was 4·98 millions per c.mm. He was now able to get out of bed alone, and stand upright by steadying himself slightly. He could walk about the ward easily with two hands resting on a chair. Memory had greatly improved and his handwriting was better. Visual acuity had increased so much that he was now able to read a newspaper easily. The urgency of micturition had ceased, and numbness and tingling had disappeared from the legs. The lower limbs showed an increase in power, with much improved coördination. Reflexes were unchanged and joint sense only slightly improved, but there was a partial return of vibration sense in the toes, tibiæ, and ilia. He has continued to improve at home, and now after four months of brain diet, about 480 g. a day, he walks alone on crutches.

Noteworthy is the rapidity of the neurological improvement, affecting memory, vision, sphincter control and vibration sense in addition to gait, coördination, and paræsthesiæ.

CASE 3.—A plasterer, aged 50, entered the hospital with subacute combined degeneration of six years' duration. Symptoms referable to anæmia began two years before entry. For the past six months he had taken, regularly, about 480 g. of raw liver daily. His general condition and anæmia had improved markedly, but the neurological condition had progressed unfavourably.

At the *commencement of brain diet* red cells numbered 4·0 millions per c.mm. He could not stand, and needed the assistance of two persons to walk even a short distance. Numbness and tingling involved the fingers and palm of the hand, and the legs up to the waist. There was a central scotoma in each visual field, possibly attributable to tobacco. Micturition was difficult at times, with urgency. Examination of the upper limbs showed some loss of power, impaired coördination, absent vibration sense in the hands and at the wrist, grossly defective joint sense in the fingers and very marked impairment of stereognosis. The deep reflexes were exaggerated with positive paradoxical flexor-extensor response. The lower limbs showed loss of power with increased tone, gross incoördination, loss of joint sense in the toes, complete loss of vibration sense below the waist, and impairment of skin sensibility to pin-prick or light touch below the knees. The knee- and ankle-jerks were exaggerated, with patellar and ankle-clonus, and the plantar reflexes were "extensor" in type on stimulation of either outer or inner sides of the soles of the feet; Oppenheim's sign was positive on the right side. The basal metabolic rate was minus 19 per cent.

Raw ox brain, 480 g. in orange juice, was given daily and liver therapy discontinued.

After four weeks the red cell count had diminished gradually to 3·6 millions per c.mm. Power and coördination of the legs were much improved. He was able to stand alone for short periods, and to walk well with a chair. Numbness and tingling had decreased in intensity and in extent, now reaching only as high as the knees.

After eight weeks the red cell count had fallen to 3·2 millions per c.mm., but he continued to improve neurologically. Strength and coördination of the limbs were increased, visual acuity was greater, and stereognosis had improved. There was a return of vibration sense in the hands but not in the legs, and some return of joint sense in the fingers. The legs were less spastic, deep reflexes were less active, and Oppenheim's sign was negative.

After ten weeks, however, he had a relapse following an upper respiratory infection in which the red blood-cell count fell to 2·8 millions per c.mm. and in which the neurological symptoms also increased. Finally brain treatment was abandoned in favour of liver extract parenterally.'' He has received intravenously, over a period of seventeen weeks, extract derived from a total amount of 2110 g. of liver, and subsequently, by the intramuscular route during a period of four weeks, extract derived from 250 g. of liver. The red blood-cell count reached 4·9 millions per c.mm. after seven weeks, during which time there was considerable decrease in extent and degree of paræsthesiæ. In spite of this somewhat intensive course of liver treatment, although there was considerable gain in strength and improvement in general health, which enabled him to walk more readily with a walking chair, neurological signs remain unchanged and he is still unable to stand alone.

This case showed remarkable neurological improvement with brain diet, although the symptoms had progressed while taking similar amounts of whole liver. The improvement took place in spite of the fact that the red blood-cell count was falling. The relapse which subsequently occurred, affecting both the blood and neurological symptoms, appeared to be due to the upper respiratory infection. The subsequent administration of liver extract parenterally brought about improvement in the blood and in the general condition, but apart from a decrease in paræsthesiæ, there have not been, as yet, any signs of neurological improvement since the relapse.

CASE 4.—A pedlar, aged 69, male, first had symptoms referable to anæmia three years previously, with neurological symptoms for the past two years. Liver treatment was begun at the time of onset of the anæmia, but had at first been irregular. For the past seven months, however, he had taken about 480 g. of raw liver daily, missing never more than one or two days per month. Although his general condition was excellent, and the anæmia had disappeared, the neurological symptoms had become severe.

At the *commencement of brain diet* the red cell count was 4·8 millions per c.mm. The basal metabolic rate was minus 9 per cent. and his weight was 227 pounds. He was unable to stand unaided, and required assistance to walk even a few steps and to get in and out of bed. Micturition was difficult, with urgency at times. Numbness and tingling æmia.[2] The presence of an achlorhydria has led ıny to suppose that the abnormal blood picture seen but an early and immature manifestation of rnicious anæmia, and as a consequence it is often ıght that the nervous changes may precede the lly formed blood picture. The introduction of 'er therapy has distracted our attention from the :t that the blood picture in many cases never ıtures into one of typical pernicious anæmia, since is believed that treatment with liver has prevented is. Thus what appears to be a most important thological feature of the disease has not been fficiently emphasised.

Since 1930 it has been shown by L. J. Witts[3] d others that achlorhydria is associated not only th primary or macrocytic anæmia, but also with condary, chlorotic, or microcytic forms. The acrocytic anæmia, as we know, responds to liver erapy, whilst the microcytic anæmia makes good coveries under large doses of iron. In the Medical nit at St. Mary's Hospital this latter mode of eatment, advocated by Witts, has been employed r several months and results obtained which amply stify the claims made for it; when liver treatment as failed, several cases of microcytic anæmia with chlorhydria have made complete recoveries by the lministration of large doses of Blaud's pill.

W. B. Castle[4] in a series of classical experiments as demonstrated that it is a deficiency in gastric :cretion which is responsible for the changes in the lood picture in macrocytic anæmia, but at present ıe reason why, given a primary achlorhydria, either ıacro- or microcytic anæmia may develop is ndecided; nor do we know what circumstances etermine how the blood picture will shape.

Bearing these considerations in mind, it seemed to ıe just possible that in subacute combined degeneration iron might be more essential than liver in the reatment, although it was realised that iron in large osage must have been used previous to the introuction of liver therapy, without, apparently, ny marked beneficial result. It was therefore letermined to apply *massive* dosage, provided that ıo toxic symptoms developed, and grs. 150 of Blaud's ill a day have been given without harmful effects.

Since only four cases have been treated, an estimaion of its value must be of a purely tentative nature, out the excellent results achieved in three out of the four cases, and the marked improvement made by the fourth, suggest an element of truth in our hypothesis. Some difficulty has been found in trying to collect many cases of subacute combined degeneration, in which the signs were sufficiently developed to establish the diagnosis with fair certainty, but as no reference elsewhere to treatment by "massive iron" therapy has been found, the results obtained by this method seem worthy of record in order that it may be given a more extensive trial.

CASE RECORDS.

CASE 1.—A man, aged 62, sent up by his doctor on Oct. 17th with a diagnosis of cerebellar disease. Discharged from work two years ago, owing to his ataxia and danger of falling into the machines which he was working. For the last six months he had grown steadily worse, and on admission could not walk more than a few yards without stumbling or holding on to objects for support. After being in bed for two days, he could not walk without falling over. Rombergism well marked. Complained of stumbling about, giddiness, weakness of legs and arms, pins and needles in hands and feet. Some incontinence of urine. Legs drawn up involuntarily in bed at night.

Examination showed diminution of tactile sensation in many areas. Temperature sensation impaired on lower jaw and left forearm. Absence of vibration sense below right knee. Some lack of positional sense. Deep reflexes of arms and legs exaggerated, more so on the right side. Positive Babinski on left side, and doubtful on right. No ankle-clonus elicited. Complete achlorhydria present. Cerebrospinal fluid tests were all negative; Wassermann reaction negative. Blood count on admission showed hæmoglobin, 68 per cent.: red cells, 3,330,000: colour-index, 1·0; and white cells, 9600. No polychromasia or nucleated red cells present.

Patient was treated by administration of Blaud's pill grs. 50 three times a day. He was allowed up only in the evening, and no massage or exercises were given. No liver was given in this case. Three weeks after admission he could get straight up out of bed and walk with very little ataxia. Five weeks after admission he was able to walk up and down a few stairs without holding on to the banisters. Seven weeks after admission he insisted on going home, as he said he felt quite well. Seen ten days later, when he walked up and down two flights of stairs without any visible sign of ataxia. On examination sensation was normal over the whole body, all thermal sense restored and use of hands much improved. He had lost all feelings of pins and needles in his hands, but vibration sense had not completely returned to his right leg, though he could now appreciate its presence. There was still some weakness of right arm present and exaggerated reflexes in right arm and knees. Left Babinski now flexor, but the right still doubtful. Sphincter trouble gone. Was thinking of returning to work in February. Blood count showed Hb. 70 per cent.; red cells, 4,400,000: C.I., 0·8; white cells, 6400.

Seen again after Christmas, he said he went over to party at friend's house and feels rather tired, but is still walking perfectly well.

CASE 2.—Woman, aged 36, sent up for anæmia by doctor who had been treating her with liver for some time, but without the patient making any progress. On examination on Nov. 26th she was seen to be anæmic, Rombergism was present to a marked degree, and she swayed helplessly when asked to walk along a straight line. Complete absence of vibration sense in both legs. Both knee-jerks were exaggerated, the right more so than the left. Babinski's sign absent; no ankle-clonus. This appeared to be an early case of subacute combined degeneration. Treated with Blaud's pill grs. 50 three times a day, and liver therapy which had been used by her doctor was continued. Not allowed out of bed for a fortnight and no massage given. At the end of a fortnight she was allowed up and asked to walk. Rombergism was now absent and patient could walk along a straight line. Put in bed another week: condition still more improved at the end, and could walk along a straight line placing one heel in front of preceding toe, a severe test for coördination, with ease. All signs have completely cleared up, and vibration sense is now appreciated in both legs, where before it was totally absent. Blood count has risen from Hb. 30 per cent.; red cells, 1,830,000: C.I., 1·1: white cells, 38,000; (relative lymphocytosis), to Hb. 74 per cent.; red cells, 3,270,000; C.I., 1·1; white cells, 7000. Patient is still under treatment for the anæmia. She says that all feeling of heaviness and stiffness has left her legs.

CASE 3.—Woman, aged 50, admitted to Medical Unit in June, 1931, complaining of pain in back and some tingling in fingers. She also said that she was unsteady and could not walk any distance without becoming tired. On examination the gait was found to be slightly ataxic, Rombergism was present but not marked, and vibration sense was lost in both legs. The reflexes were all normal except for exaggeration of the right knee-jerk. Complete achlorhydria present and blood count showed Hb., 39 per cent.; red cells, 4,300,000: C.I., 0·4; and white cells, 5000. Diagnosed as a case of subacute combined degeneration. Massage for legs and full liver diet were given, and patient was sent out on the liver diet, having made some improvement.

Written for on Nov. 14th to try the effect of the new treatment. She now complained that she could not walk more than a mile without her right foot turning over, and her husband said that when this occurred she became very ataxic, and he had experienced some difficulty in getting her home. She had not been able to do any housework or cook the meals. Additional signs were now present in spite of the liver treatment. The right leg gave a positive Babinski sign and both ankle-jerks could only be elicited with great difficulty; the knee-jerks were not exaggerated. Absence of vibration sense was present as high as the mid-thoracic region of the spinal column. Frequent attacks of incontinence of fæces were also occurring.

Treated with Blaud's pill grs. 50 three times a day for three weeks in the ward and since then as an out-patient. A marked improvement in general health has occurred; her husband reports that he accompanied her on a three-mile walk and no signs of ataxia or weakness of the leg developed. She has only had one attack of incontinence of fæces since returning home. Vibration sense has returned as low down as the mid-lumbar region, but it can only be very feebly

DISCUSSION.

The results obtained suggest that ox brain may exert a beneficial effect upon the neurological phenomena of pernicious anæmia. It is necessary to decide how much of the improvement can be attributed to the effects of brain diet. Although Oppenheim[9] and Curschmann[10] believe that, in the absence of treatment, "natural" remission of the neurological manifestations may occasionally happen, such an event must be extremely rare, and Collier[11] states that "any improvements which occur are improvements in the general health and in the anæmia, rather than any lessening of the gravity of the nervous manifestations." Russel[12] expresses a similar opinion. It therefore seems unlikely that the neurological improvement during brain therapy could be attributed to spontaneous remission.

The question also arises as to whether the improvement which occurred in six of the nine cases during brain treatment could be attributed to an effect carried over from the previous liver therapy. In four patients (Nos. 3, 4, 5, and 6) liver treatment had been taken without significant neurological benefit for sufficient lengths of time to rule out any likelihood that, in the absence of brain diet, improvement would have commenced after liver had been discontinued. In two cases (Nos. 1 and 2), however, the periods of administration of moderate to large amounts of liver (240 to 700 g. daily) which preceded the brain treatment were relatively short—namely, 13 weeks in one case and six weeks in the other. In the longer of these periods, at least, one would expect some, although not maximal, neurological benefit. But since, during the administration of liver for these lengths of time, one patient had shown no improvement whatever, and the other had become worse, and further, since improvement promptly occurred during subsequent brain therapy, it is very improbable that the beneficial effect could be attributed to the liver previously ingested. Moreover, the fact that neurological improvement continued for six months and four months respectively, with brain diet in the absence of liver, is further evidence that this benefit is unlikely to have been a remote result of the previous liver treatment.

With regard to the three patients who did not improve, it should be pointed out that one, who was in the terminal stages of the disease, with complete paraplegia in flexion and incontinent sphincters, was also suffering from urinary sepsis and bed sores. Such complications have been shown to adversely affect the response to liver therapy of the neurological condition.[2 3] It is known that, even in the absence of septic complications, there are certain cases of subacute combined degeneration which fail to show neurological improvement when treated with large amounts of whole liver over periods of many months.[2] This lack of response may perhaps be due to defective absorption or utilisation of the active principle or to its destruction in the gastro-intestinal tract. Some such explanation possibly accounts for the lack of improvement in the other two patients, one of whom had already failed to respond to 240 g. of raw liver taken daily for five months.

In the improved cases the effect of brain appeared to be greater than that of the liver previously taken, but only in Cases 3 and 4 were the amounts of liver and brain in any way comparable weight for weight. The evidence is as yet insufficient for any accurate comparison of the relative potencies of liver and brain for producing neurological benefit.

However, if the hæmopoietic potency of ox brain is taken as about one-third that of liver, then six out of nine cases improved neurologically on a diet which was less potent for blood regeneration than that of the previously ingested liver. This is also emphasised by the fact that in all cases, except Nos. 2 and 6, the red cell count diminished during the period of neurological improvement.

If the results are confirmed, it would appear that the effect of brain diet upon the nervous system is markedly disproportionate to its effect upon the bone-marrow, when compared to the relative effects of liver upon these two systems. The findings tend to support the hypothesis that the effect of organ therapy upon the nervous system in this disease is not wholly the result of maintenance of the red blood-cell count at a high level, and that there may exist in liver and in brain a factor beneficial to the lesions in the nervous system, distinct from that which influences the regeneration of blood. Mellanby[13] has suggested that fat-soluble-A may be the factor responsible, but brain contains little or none of this vitamin.

Owing to its low potency for blood regeneration brain is not suitable for the routine treatment of subacute combined degeneration unless combined with amounts of liver or potent substitute adequate to maintain a normal blood picture.

I am indebted to Dr. J. B. Ayer, Dr. J. H. Means, and to Dr. J. Lerman at the Massachusetts General Hospital for their helpful coöperation. I am indebted also to Dr. G. R. Minot and Dr. Stanley Cobb fo allowing me to treat cases in their wards at the Boston City Hospital.

TREATMENT OF

SUBACUTE COMBINED DEGENERATIO OF THE CORD

BY MASSIVE IRON DOSAGE.

BY WILL SARGANT, B.CHIR. CAMB., M.R.C.S. ENG

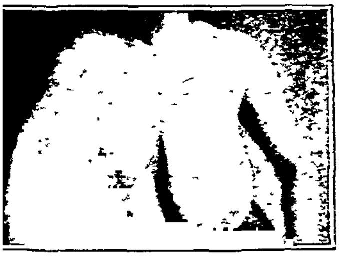
HOUSE PHYSICIAN TO THE MEDICAL UNIT, ST. MARY'S HOSPITAL, LONDON.

IT has now come to be recognised that in the trea ment of subacute combined degeneration of the co liver therapy is usually of little or no use, in fa the disease often progresses in spite of its administra tion. Of late, various experimenters have gone in new fields of research in an attempt to find some oth factor at work to produce these nervous change Prof. E. Mellanby,[1] for instance, has publishe research which inculpates vitamin A deficiency.

Several observers for many years have pointed ou that in cases of subacute combined degeneration, th blood picture is rarely that of a typical pernicio ing skin is flushed and feels hot to the touch. The ysical signs are those of a diffuse inflammation, as om a mild grade of infection or from a premature ortive attempt at lactation. Sometimes a little ear milky fluid can be expressed from the nipple.

As may be expected, the condition often causes arm to the parents and distress to the patients. hilst it is true that these inflammatory signs usually bside spontaneously in the course of a few months, the breast returning to a size within the limits of normality, occasionally it remains unduly large and heavy, the gland itself harder and more sharply defined than is normal. Sometimes, no doubt, return to the normal is ultimately reached by way of lactation later; e residue probably constitute those cases of massive ypertrophy which require treatment in adult life.

FIG. 1.



rue hypertrophy of corpus mammæ. Result of first operation.

In the pendulous, flaccid breast which sometimes llows lactation the gland itself is merely prolapsed, nd the condition is so classified by Dartigues,[1] who as written extensively on this subject. There is no ypertrophy of the gland tissue; no symptoms, as a ule, ensue, and treatment is not invited unless the atient, for purely æsthetic reasons, demands correcion of what may seem to her a deformity from which he considers she has the right to escape.

In quite a different category are those cases in hich there is a true hypertrophy of the corpus mammæ, breasts so grossly enlarged (Fig. 1) that hey constitute a burden and a handicap to their nfortunate possessors. So enormous may these ecome that they rest upon the lap of the patient when he is seated. The mere weight and bulk of the breasts ften cause a stooping gait—according to Dartigues an actual kyphosis. There is usually some tenderness on palpation, the superficial veins are unduly prominent and the skin dusky, even cyanosed, particularly around the nipple, which is always displaced towards the lower pole of the breast. Pain, dull. aching and dragging in character, is almost invariable, compelling the patient eventually to seek relief. In the majority no discrete tumour can be felt, but many are manifestly affected by a mazoplasia or a cystic mastitis; indeed, it is doubtful if any mammary gland so excessively enlarged can be regarded as healthy, a fact which influences decisively the manner of treatment necessary. Mental depression is a frequent concomitant, varying widely according to the temperament of the individual, and may, according to Kausch,[2] induce suicidal tendencies.

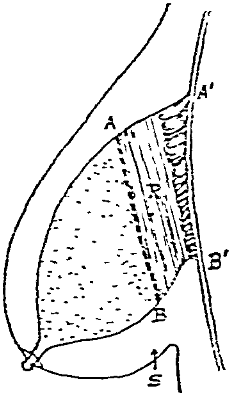
THE EFFECTS OF STASIS.

The tissues of such breasts must clearly suffer deleterious effects from stasis of their circulation and secretions, the penalties of which have been emphasised in recent years by various authors—e.g., Cheatle and Adair et al.[3] The mechanical supports and tight bandaging commonly employed to mitigate the uncomely appearance and physical discomfort aggravate this tendency to stasis. Ewing [4] assigns to stasis the rôle of principal predisposing cause of cancer in the breast, whilst the experiments of Adair et al.,[3] who artificially induced stagnation of milk in 15 mice, producing thereby metastasing tumours in 13, strengthen the belief that in these extremely large human breasts stasis must cause serious changes in their tissues.

In all the mammæ on which I have operated for hypertrophy of the gland, as distinguished from mere prolapse of a more or less healthy gland, the condition had been present for several years, growing slowly but steadily worse; in all there was definite disease, suspected though not demonstrable before operation, namely "mastitis," "cystic mastitis," or "intracanalicular fibro-adenoma" according to the reports of the pathologist. It appears, therefore. that any operation which does not include removal of the gland will be inadequate.

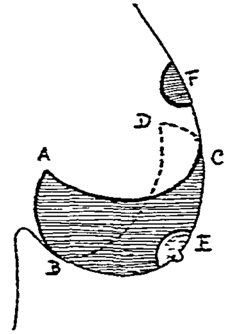
The numerous ingenious operations devised by American and continental surgeons consist, in principle, of a suspension of the corpus mammæ at a higher level. Some diminish the size of the breast by sacrificing part of the fatty capsule, some do not hesitate to take away a discoid or cuneiform portion of the gland itself to achieve an æsthetic result. All agree that preservation of the nipple is essential, all deprecate the complete amputation of the breast in the manner still frequently practised in this country, the results of which are illustrated in my previous paper.[5] So ruthless and summary a method is neither desirable nor necessary. Dartignes claims that operations for æsthetic reasons are essentially French in conception and he coins a curious phrase, the "disgrâce mammaire." He describes four degrees, and his procedure varies accordingly from merely anchoring the gland through a small axillary incision to complete amputation. He considers this last justifiable only for the most severe grades. By the operation which I have evolved the necessity for this latter course can be obviated. Dartignes favours for most cases the operation of Morestin (Fig. 2) which, however, he asserts was first described by Aubert of Marseilles in 1923.

FIG. 2.



Morestin's operation. Case of symptomless enlargement of left mamma in a girl of 17. No disease. S = line of semicircular incision. R = Shaded area representing amount of corpus mammæ removed. A then stitched to A′ B then stitched to B′.

FIG. 3.



Passot's operation. Incisions A C D (upper) and A B D (lower). Then circular incision E around areola and excision of circular area F, removal of skin and subjacent fat in area A B C D (shaded area) freeing of corpus mammæ to allow lifting of nipple into gap F where it is sutured. Note: sometimes he found it necessary to remove the whole corpus mammæ, more usually he excises a discoid portion to reduce the size of the corpus mammæ.

Morestin[6] attempts to preserve the corpus mammæ, but confesses that he has often been compelled to remove a discoid portion (R), sometimes the whole appreciated in the left knee. The right leg still gives a positive Babinski sign, but the ankle-jerks are now easily elicited. Blood picture is Hb. 80 per cent.; red cells, 4,440,000; C.I., 0·9; white cells, 5000. She has again resumed the cooking and housework for the family, and finds no disability from what physical signs she has remaining.

CASE 4.—A nurse, aged 58 years. In May, 1930, began to find difficulty in keeping her balance and doing delicate movements with her fingers. Tingling and pins and needles in her hands. Had to give up work owing to unsteadiness and weakness of the legs. Admitted under Medical Unit in April, 1931. Rombergism was marked, total loss of vibration sense in both legs, and slight weakness of tactile sensation in right leg. Abdominal reflexes lost; bilateral positive Babinski and exaggerated reflexes of legs and arms. Some slight incoördination of arm movements and loss of positional sense in toes. Blood picture showed Hb. 84 per cent.; red cells, 3,600,000; C.I., 1·1; and white cells 9100 with no relative lymphocytosis. Complete achlorhydria present. Cerebrospinal fluid and Wassermann test revealed nothing. Treated with liver and Radiostoleum with some slight improvement. Sent out to nursing-home and from there to rest at home in Suffolk. Here she found that she could only walk with the aid of a stick and had frequent falls.

Written for to return, owing to success of previous cases, and on admission was unable to walk without continually steadying herself by holding on to articles of furniture. Immediately on leaving bed was completely ataxic.

She was treated with Blaud's pill grs. 50 three times a day, and the liver treatment was continued. No massage or any other treatment was given. Very little improvement for three weeks, then a sudden improvement took place. Can now walk round ward and negotiate obstacles placed in her path with very little ataxia, and needs no help at all. Gait still slightly spastic, but otherwise general power of walking is good even on immediately rising from bed. Pins and needles now absent, though these had not been a prominent symptom for some months. Only slight return of vibration sense in left ankle, but good sensation in right leg. Reflexes still exaggerated, but left Babinski is only doubtfully positive. Rombergism now practically absent, and positional sense of toes much better. Patient cannot yet walk up and down stairs without help, but is improving rapidly, while general health is markedly better. Blood count was Hb. 98 per cent.; red cells, 4,930,000; C.I., 1·0; white cells, 8000. Total length of treatment with iron since admission is six weeks.

It will be seen that the clinical improvement in three out of four of these patients was most unusual; in the fourth, who was not markedly ataxic, some improvement occurred in her general power of walking, return of vibration sense and loss of sphincter trouble. In all four cases, only one presented a blood count that resembled pernicious anæmia, but all four had complete achlorhydria. It seems to be essential to continue treatment without remission for at least six weeks before it can be regarded as having failed. All the patients are still taking their large doses of iron at the time of writing, and they will only be reduced when we are certain that maximal improvement has taken place. None of them are experiencing any unpleasant symptoms from the treatment.

From the nature of the pathology of the disease, it is not to be expected that all signs will clear up, for nerve tissue, once destroyed, cannot be regenerated. The chief result must necessarily coincide with the earliest period of the disease, when the morbid changes are essentially those of œdema of the medullary sheaths. It must be due to the fact that there was no actual degeneration of axis cylinders that two out of the four patients who were unable to walk without stumbling are now able to do so, that their ataxia and the other nervous features of their malady are so greatly improved. In all, the sense of well-being and general health is remarkably better.

I have to thank Prof. F. Langmead most sincerely for allowing me to carry out these investigations under his supervision and help. Dr. Wilfred Harris has also seen the cases and has advised a preliminary publication of what has been achieved. It is hoped that this will prompt others to carry out what is essentially an easy treatment, and to report on the results so that its value can be more accurately assessed. In spite of the small number of cases treated, the results appear to warrant the conclusion that the procedure may be a definite contribution to the treatment of a disease which has always provided a difficult therapeutic problem.

SUMMARY.

1. Liver therapy in subacute combined degeneration having generally failed, it was decided to seek for some other factor in its causation.

2. The fact that many cases did not present a typical primary or macrocytic type of anæmia, but rather a secondary or microcytic anæmia combined with an achlorhydria suggested the use of iron.

3. It was decided to give "massive dos[illegible]" because it was thought that iron in large doses [illegible] have been used previous to the introduction of liver therapy.

4. Blaud's pill, grs. 150 a day, was given to four patients with strikingly beneficial results. Two who were not able to walk unaided can now do so, and the other two, in whom the disease was not so advanced, have been greatly improved. No other accessory treatment, except the continuation of liver diet in three cases, has been given.

To simplify administration, Blaud's pill has been made up in powder form in capsules. The dosage is three capsules three times a day, equivalent to grs. 150, given with a little water.

MASSIVE ENLARGEMENT OF THE BREAST.

BY H. H. GREENWOOD, M.B., B.S. LOND., F.R.C.S. ENG.,

CHIEF SURGEON TO THE GREAT WESTERN RAILWAY HOSPITAL, SWINDON.

AMONGST the lesser ills that afflict the body enlargement of the mamma beyond the limits o physiological necessity, to such a degree as to embarrass and distress the possessor, presents a problem o interest and of some importance.

Perhaps the condition is less common, perhaps vanit is less of a cardinal virtue in this country; certai it is that little more than a casual consideration seem to have been given to the problem here; and it i necessary to turn to the literature of America, Franc Germany, and Italy to find any serious treatises o the subject. This lack of interest, as reflected in ou literature, probably arises not so much from an rarity of the disease, as from the fact that treatment i usually summary—a sweeping removal of the enlarge organ regardless of all æsthetic considerations, procedure which is adequate but far from ideal.

One variety of excessive development of the breas the hypertrophy of pubescence, not infrequentl arises in sturdy adolescents of agricultural parentag who have been translated to urban surrounding The pathology of the condition remains obscur Beginning at the onset of puberty, though sometim occurring in virgins of more mature age, the diseas affects one or both breasts. Usually the left is th more severely affected. The breast becomes undul enlarged, tense, painful, and sensitive to the lighte touch. Pain is variable in degree; usually it is achin or even throbbing in character. Sometimes the ove

ULCUS TROPICUM,

WITH A REFERENCE TO ITS TREATMENT BY X RAYS.

BY T. R. F. KERBY, M.R.C.S. ENG., D.M.R.E.

lcus tropicum is mentioned as early as 1792 by nter in Jamaica. His description is in general eement with that given in this paper. After 1792 nerous references are to be found, usually iden-ing the ulcers with the part of the world in which observer has seen them. Later it became obvious t the condition was widespread and not localised one particular geographical area. It has numerous onyms but to-day they are seldom used. Among er names are the following: Yemen ulcer, Aden er, Cochin sore, Mozambique ulcer, Sarmes (Congo), l Phagedæna tropica.

The condition is found in all tropical and sub-pical parts of America, Africa, and Asia. It is y much more common in men than in women and ldren. Indeed, to see a tropical ulcer in a woman child is, in my experience, quite rare.

ÆTIOLOGY.

The assertion is repeated in many text-books that us tropicum is frequently a tertiary manifestation syphilis or yaws. With this I do not agree, except so far as it is possible that an untreated tertiary philide might, by superinfection, become a tropical er. In my experience, antisyphilitic measures ve little therapeutic value in tropical ulcer and there ould be little room for error if the Wassermann action is taken in all doubtful cases.

Vincent has found fusiform bacilli and spirilla in ears from these ulcers, and Prowazek, Holbach d Todd attach some ætiological significance to the *irochæta schaudinii* (Prowazek, 1907), a very active otile spirochæte 10-20µ in length with a well-arked undulating membrane and a short flagellum. was suggested that this organism was transmitted a leech but, on inquiry, I can find no evidence sociating the occurrence of tropical ulcer with leech ites in Northern Rhodesia. I regret that no bacterio-gical work on this question has been possible as yet this country. All that can be said from observa-ons here is that in a smear from any tropical ulcer arious micrococci, bacilli, spirochætes, and fusiform acilli have been seen.

The starting point of an ulcer is always, in my xperience, a scratch, wound, or insect bite, and fre-uently one finds a new ulcer arising from the site of n old ulcer previously treated. The assumption, in y opinion, is that secondary infection has super-ened on the primary trauma.

With these local causes it is nearly always found hat the ulcer is in an exposed position—e.g., leg. sually—on a poor adult male with naked legs and eet. In this connexion it is interesting to observe hat the incidence of ulcus tropicum among the native mployees of the Rhodesia railways has decreased normously wherever the wearing of puttees has been nsisted upon. It is usual to find that the patient's esistance is lowered by debilitating diseases such as nkylostomiasis, malaria, scurvy. or filariasis, which are so widespread in tropical Africa.

Tropical ulcer and veld sore are now regarded as two separate conditions. The differential diagnosis can be difficult, and no work has been done in this country on the association of the *B. diphtheriæ* with veld sore. But treatment by antidiphtheritic serum is rapidly successful in a true veld sore and has no effect on a tropical ulcer.[1]

For a paper, followed by a discussion, on attempts to grow the *Spirochæta schaudinii*, with inoculation experiments, those interested are referred to Smith.[2]

Diet and calcium deficiency seem to have a very considerable ætiological significance. The well-fed and well-paid native is rarely found with a tropical ulcer. In my practice all these cases are put on a generous diet immediately on admission; calcium and cod-liver oil are administered daily, and any inter-current disease is treated.

PATHOLOGY.

Unfortunately, no distinctive features have been found on pathological examination. A mass of granulation tissue is seen, usually covered by a fibrinous layer containing detritus and spirochætes and bacteria, together with some eosinophil leucocytes. Only once has a tropical ulcer been proved to be communicable by inoculation. This was done by Lloyd Patterson,[1] who bandaged a swab smeared with discharge from an ulcer on to an abrasion from which the scab had been removed, and succeeded in producing a tropical ulcer. Interesting confirmation of the view that these ulcers are communicable is found in the fact that officials touring from village to village report that in most villages no tropical ulcers are seen and then in one isolated village a series of six or more will be found. My own impression, entirely unconfirmed by any bacteriological or entomological work, is that the infection is, in all probability, carried by flies. If this is so it should be possible, by preventing access of flies to the ulcers, to prevent spread of infection from them to clean wounds in the same ward. In practice I have found this to be the case, and prophylaxis therefore will depend on protection of the skin from abrasions and, when abrasions occur, the immediate application of antiseptic dressings. This is, in substance, the prophylaxis that has been used in this territory for some years now, and if properly applied it is undoubtedly successful.

Healing is apparently never spontaneous, and in any case is always slow and proceeds by granulation from the periphery, leaving a thick white scar which at first is soft and easily broken down, with a consequent renewal of the ulceration.

SYMPTOMS.

At the outset there is a painless swelling which is soft and may be fluctuating. Then a break in the skin is seen from which a serous discharge exudes. This is followed by rapid breaking-down into an ulcer with raised, thickened edges. The ulcers are usually single and rounded but may be multiple. A greyish-yellow, foul-smelling slough now forms and, if no treatment is given, the ulcer rapidly deepens. It may also extend laterally, and there is an occasional tendency to the serpiginous type, but usually the spread is by increase in depth, so that in a remarkably short time muscles and tendons are involved and periostitis develops. This may lead to a diffuse osteitis and osteomyelitis with huge involucra and sequestra, as a result of massive necrosis. Subsequent contractures and deformities are most disabling. On occasion, the untreated case progresses to septicæmia and death.

VARIOUS METHODS OF TREATMENT.

It is a remarkable fact that very little space is devoted in the standard works on tropical medicine gland, to obtain a satisfactory result. This procedure is dictated solely by the necessity to reduce the bulk of the mass, and not from any conviction that the gland is diseased and therefore superfluous. Raymond Passot [7] (Fig. 3) similarly preserves the gland wherever possible, but sometimes has to remove a discoid slice from the base of the gland to lessen the bulk. The plan of this operation is ingenious, and good æsthetic results are claimed for it. Dowkontt[8] (Fig. 4) leaves the corpus mammæ intact. After removal of a circular strip of skin and subjacent fat, he suspends the gland at a higher level by suturing the upper and outer rim to the aponeurosis covering the pectoral muscles and then unites the skin edges. Again the æsthetic results appear to be admirable, but a scar is left over the upper part of the breast at its junction with the chest wall. Moreover, this operation does not seem adequate for any but the milder grades of the affection, and could scarcely be applicable to those cases in which the weight of the corpus mammæ itself is from 2 to 4 lbs.

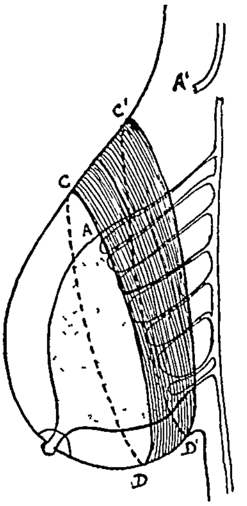
---

[1] Manson-Bahr, P.: Manson's Tropical Diseases, 1925.

[2] Smith, E. C.: Proc. Roy. Soc. Med. (Sect. Trop. Dis.), 1930, xxiv., 1.

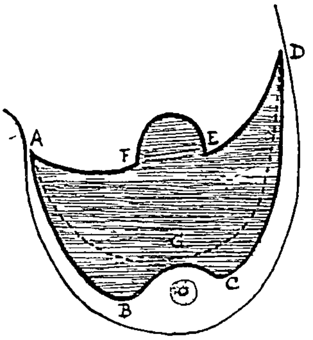
If my contention be true that in all these cases where intervention is justifiable the organ is hopelessly diseased and useless for lactation, it is necessary to make removal of the gland itself an essential part of the operation. Accepting this as axiomatic, I devised and have employed the following operation in which the corpus mammæ is removed, the fatty envelope and the nipple are preserved, and by which the æsthetic requirements are satisfied.

FIG. 4.



Dowkontt's operation. By circular incisions C D : C' D', removal of skin and fatty envelope between C C' and D D', then stitching the upper margin of the corpus mammæ A to the lip of aponeurosis A raised from the chest wall by a transverse incision, and finally suture of skin edges C to C' and D to D'.

FIG. 5.



H. H. Greenwood's operation. Removal of skin over shaded area A B C D E F, incision of fatty envelope along line A G D, removal of corpus mammæ, and suture of skin edges B to F, C to E.

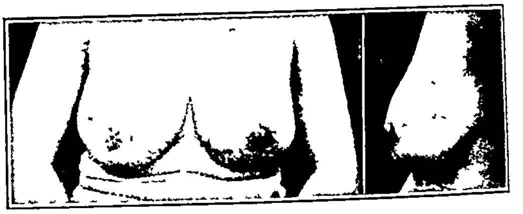
OPERATION.

In the following operation (Fig. 5), as in all those referred to above, preservation of the areola and nipple is regarded as imperative.

The operation is begun by lightly scratching on the skin a line from the nipple situated at the lower pole, upwards to the point at which it is decided that the transplanted nipple shall lie. Two curved incisions A B C D and A F E D are then made through the skin only. The lower one sweeps upwards slightly in a low curve above the areola ; in the upper curved incision a semilunar segment F E is excised, to receive later the portion B C ; the intervening portion of skin is then dissected off and removed. The fatty capsule is then incised down to the gland along the line A G D, placed nearer to the lower incision to safeguard the nutrition of the lower flap. By keeping close to the surface of the corpus mammæ the two flaps of the fatty covering can be dissected in a continuous layer back as far as the margin of the gland all round ; the bundle of lactiferous ducts, after being isolated, is severed cleanly as near as possible to their junction with the gland.

The flaps are enveloped in large moist swabs whilst the whole of the corpus mammæ is being removed ; all bleeding points are carefully secured, and a small drain leading from the cavity is inserted through a stab puncture at the most dependent point of the reconstructed breast, and left for 24 to 48 hours. The fatty capsule is now drawn together by a few fine catgut sutures, being so disposed as to reproduce as nearly as possible the contour of the normal organ. The skin edges are united by fine fishing-gut sutures or by Michel's clips. Abundant dressings and moderately firm bandaging limit effusion and add greatly to the comfort of the patient.

FIG. 6. FIG. 7.



Photographs from same case as Fig. 1. Result of second operation.

The photographs (Figs. 1, 6, and 7) are from a patient, aged 37 years, nulliparous, in whom the slowly increasing weight and painfulness of the breasts had become an intolerable burden. The first operation was done on the right breast (Fig. 1) on March 1st, 1931, that on the left side seven weeks later. The immediate result is shown in Figs 6 and 7, which indicate the substantial diminution effected in size. The latter can be regulated according to the physique of the patient. In this case the cosmetic result improved later still more, but as the patient came from a distance a more recent photograph is not available.

In the published reports of the various methods hitherto employed little comment is made on the subsequent condition of the breast as regards pain, the cosmetic result being emphasised. The five breasts on which I have operated were markedly tender and painful, and there was strong presumption of disease in the corpus mammæ, so that any operation which left the gland seemed likely to fail in an important respect. The operation I have described removes the painful diseased gland, without inflicting an irreparable deformity on a sensitive patient.

We recognise readily enough the distress caused to patients by facial blemishes or disfiguring varicose veins, and make haste to remedy these with all the skill at our command. We are apt to overlook the sensitiveness, very real though less frequently avowed, of a patient who has undergone an unnecessarily mutilating operation on the breast.

OPENING OF FALKIRK INFIRMARY.—Prince George last week formally opened the new infirmary at Falkirk which has been erected at a cost of £100,000. With the exception of the maternity home and a portion of the isolation block, which are being paid for by the local authorities, the whole of the cost has been raised by voluntary subscriptions. A considerable proportion of the total has been provided by working people, who gave twopence and threepence a week for two or three years.

gland, to obtain a satisfactory result. This procedure is dictated solely by the necessity to reduce the bulk of the mass, and not from any conviction that the gland is diseased and therefore superfluous. Raymond Passot [7] (Fig. 3) similarly preserves the gland wherever possible, but sometimes has to remove a discoid slice from the base of the gland to lessen the bulk. The plan of this operation is ingenious, and good æsthetic results are claimed for it. Dowkontt[8] (Fig. 4) leaves the corpus mammæ intact. H. H. Greenwood's operation. Removal of skin over shaded area A B C D E F, incision of fatty envelope along line A G D, removal of corpus mammæ, and suture of skin edges B to F, C to E.

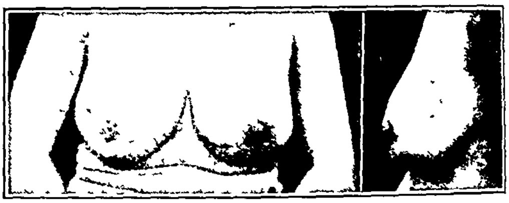
OPERATION.

In the following operation (Fig. 5), as in all those referred to above, preservation of the areola and nipple is regarded as imperative.

The operation is begun by lightly scratching on the skin a line from the nipple situated at the lower pole, upwards to the point at which it is decided that the transplanted nipple shall lie. Two curved incisions ABCD and AFED are then made through the skin only. The lower one sweeps upwards slightly in a low curve above the areola; in the upper curved incision a semilunar segment FE is excised, to receive later the portion BC; the intervening portion of skin is then dissected off and removed. The fatty capsule is then incised down to the gland along the line AGD, placed nearer to the lower incision to safeguard the nutrition of the lower flap. By keeping close to the surface of the corpus mammæ the two flaps of the fatty covering can be dissected in a continuous layer back as far as the margin of the gland all round; the bundle of lactiferous ducts, after being isolated, is severed cleanly as near as possible to their junction with the gland.

The flaps are enveloped in large moist swabs whilst the whole of the corpus mammæ is being removed; all bleeding points are carefully secured, and a small drain leading from the cavity is inserted through a stab puncture at the most dependent point of the reconstructed breast, and left for 24 to 48 hours. The fatty capsule is now drawn together by a few fine catgut sutures, being so disposed as to reproduce as nearly as possible the contour of the norma organ. The skin edges are united by fine fishing-gut sutures or by Michel's clips. Abundant dressings and moderately firm bandaging limit effusion and add greatly to th comfort of the patient.

FIG. 6. FIG. 7.



Photographs from same case as Fig. 1. Result of second operation.

The photographs (Figs. 1, 6, and 7) are from a patient, aged 37 years, nulliparous, in whom the slowly increasing weight and painfulness of the breasts had become an intolerable burden. The first operation was done on the right breast (Fig. 1) on March 1st, 1931, that on the left side seven weeks later. The immediate result is shown in Figs 6 and 7, which indicate the substantial diminution effected in size. The latter can be regulated according to the physique of the patient. In this case the cosmetic result improved later still more, but as the patient came from a distance a more recent photograph is not available.

In the published reports of the various methods hitherto employed little comment is made on the subsequent condition of the breast as regards pain, the cosmetic result being emphasised. The five breasts on which I have operated were markedly tender and painful, and there was strong presumption of disease in the corpus mammæ, so that any operation which left the gland seemed likely to fail in an important respect. The operation I have described removes the painful diseased gland, without inflicting an irreparable deformity on a sensitive patient.

We recognise readily enough the distress caused to patients by facial blemishes or disfiguring varicose veins, and make haste to remedy these with all the skill at our command. We are apt to overlook the sensitiveness, very real though less frequently avowed, of a patient who has undergone an unnecessarily mutilating operation on the breast.

OPENING OF FALKIRK INFIRMARY.—Prince George last week formally opened the new infirmary at Falkirk which has been erected at a cost of £100,000. With the exception of the maternity home and a portion of the isolation block, which are being paid for by the local authorities, the whole of the cost has been raised by voluntary subscriptions. A considerable proportion of the total has been provided by working people, who gave twopence and threepence a week for two or three years.

in saline was the only dressing applied. As I have mentioned previously, all necrotic tissue was first curetted away under general anæsthesia before the course was begun.

ZINC IONISATION.

Twenty-five cases were treated by this method. I have found it particularly useful in healing up residual areas of ulceration which, though clean and apparently healthy, refuse to granulate up and epithelialise. I have been unable to satisfy myself that this method has any great practical value in treating the large tropical ulcers ab initio, and on the whole I am inclined now to reserve ionisation for the occasional treatment of small residual indolent patches of a partially healed ulcer. For ionisation a 1 per cent. solution of zinc sulphate has been used and the current intensity has been at the rate of 2 m.a. to the square inch for 20–30 minutes.

The type of case chosen for X ray therapy was the chronic indolent type which had existed for some time or had resisted other methods of treatment. My reason for this choice was that I find that when a case comes up early it is comparatively easy to heal the ulcer by the method I have outlined, and consequently there seemed to be no necessity to use an expensive (and not always available) method of treatment. The results of X ray therapy are, in my opinion, distinctly disappointing. I have been quite unable to satisfy myself that any appreciable improvement was caused by X radiation, and the eventual healing of the ulcers treated by this method was, I think, due to the preliminary curettage and the daily cleansing of the ulcers.

Method.	Ulcers treated.	Average duration before beginning treatment (patient's statement).	Average number of days before healing was complete.	Healed.	Unhealed.
X ray therapy "A."	25	4 months	98 days	20	2 absconded. 1 died. 1 handed over to surgeon. 1 still in hosp.
X ray therapy "B."	26	4½ months	99 days	21	1 died. 4 still in hosp.
Zinc ionisation.	25	As this treatment was usually employed in conjunction with, or after, other forms of treatment, no figures can be given.			
"Bipp."	25	1 month	31 days	25	nil.
Peroxide, fomentations: eusol dressings.	25	3 weeks	51 days	24	1 absconded.

METHOD OF TREATING ULCUS TROPICUM WITHOUT PRELIMINARY CURETTAGE.

As many cases of this condition occur in native districts and are attended at dispensaries which are only occasionally visited by a medical officer, I have tried to work out a method of treatment which can be carried out with more or less success by the African orderly in charge of the dispensary. A method that has been reasonably satisfactory in the case of recent ulcers has been to give the ulcer a preliminary thorough swabbing with hydrogen peroxide (and here the orderly needs a heavy hand if the method is to be effective) followed by boric fomentations and then eusol or other dressings. This method is, however, quite unsuitable for the chronic ulcer and, in my opinion, these cases should be sent immediately to the nearest station at which there is a medical officer. A record of results of cases treated is given in the Table.

CONCLUSIONS.

1. *Prophylaxis* depends upon: (*a*) Adequate nutrition and freedom from debilitating disease. (*b*) Protection of exposed parts from trauma (e.g., labourers should wear puttees and shoes). (*c*) Prompt application of antiseptic dressings to all minor injuries. (*d*) Early application for treatment when an ulcer begins to develop. (*c*) (*c*) and (*d*) involve the provision of trained medical orderlies at dispensaries, or in villages, who will supply dressings and educate the native mind. All gangs of labourers should have a medical orderly attached to them.

Of one thing I am convinced, and that is that these ulcers should almost never occur in natives employed by Europeans. A very small amount of supervision should suffice almost entirely to prevent the occurrence of ulcus tropicum in industrial areas.

2. *Treatment.*—I favour the following routine treatment:

(*a*) As soon as possible after admission, the blood, urine, and fæces are examined and a routine physical examination of the patient is made. Treatment is begun at once for any pathological condition discovered in the examinations, and the patient is put on a liberal mixed diet with as much fruit and fresh vegetables as possible. If no other drug is found necessary (to treat intercurrent disease), calcium lactate and cod-liver oil are prescribed. The patient remains in bed, and the bowels are kept well open.

(*b*) Under general anæsthesia the ulcer is curetted with a blunt curette and the undermined and indurated edges are clipped away with scissors. All pockets are well opened and, if necessary, the bone is scraped and sometimes the medullary cavity will require to be opened.

(*c*) Bipp is now packed into the ulcer, lint applied, the limb firmly bandaged, and the patient returned to bed. The number of times Bipp is repeated is a matter for the discretion of the medical attendant in the individual case. It rarely needs repeating after five or six days.

(*d*) Wet eusol dressings are then applied twice daily until the ulcer is healthy and clean and a fine ingrowth of new skin begins to appear.

(*c*) Zinc oxide strapping is then applied so that an area of one inch around the ulcer is included. This is left in situ for a week, at the end of which time it is removed, the ulcer is cleaned up with eusol, and the strapping is reapplied. About this time the patient is usually allowed to get up and stroll about the grounds. In some cases he is now allowed to come up as an out-patient.

In conclusion, I have to express my thanks to Dr. P. H. Ward, Director of Medical and Sanitary Services in this territory, for permission to carry out this work in the Native Hospital, Livingstone. I have also to thank the staff, both European and native, of this hospital for their assistance. I must also apologise for the lack of references and express my indebtedness to the authors of Manson's "Tropical Diseases," Byam and Archibald's "Practice of Medicine in the Tropics," and Castellani and Chalmers' "Manual of Tropical Medicine."

Livingstone, Northern Rhodesia.

Durham County Hospital.—The scheme of reorganisation proposed by Dr. Charles Franks, the county medical officer of health, proposes the reduction of the number of isolation hospitals from 28 with 700 beds to 12 with 582 beds, and that there should be three small-pox hospitals instead of ten. Dr. Franks found that in 1930 the beds were occupied on only 138 days. The reduced beds would thus still leave a sufficiently large margin to deal with any moderate epidemic. Extensions of the remaining hospitals could be made economically.

to this disabling condition. This can, I think, only be explained on the supposition that no really satisfactory treatment has yet been evolved, and no specific treatment is possible owing to the general doubt regarding ætiology. It is for this reason that, as suggested in Manson's "Tropical Diseases," I decided to try the effect of X ray therapy. Before discussing a series of cases treated by radiotherapy I propose to outline the more generally used methods of treatment.

An essential preliminary to any form of treatment is to cleanse the surface of the ulcer. This may be done either by using powerful caustics, such as pure carbolic acid, or by curettage. Personally I prefer curettage under local or general anæsthesia, and I regard it as essential to remove all sloughing and unhealthy tissue and also to cut away with scissors the undermined and overhanging edges. All my cases are treated in this way and, in my view, it is useless to hope to heal one of these ulcers unless a thorough preparation of this kind is first undertaken.

Another feature which must be common to all forms of treatment is the elimination of any intercurrent affection of the type mentioned under ætiology. With this goes the natural corollary that a generous mixed diet with an abundance of green vegetables and fresh fruit must be ensured.

The only drug I use now is calcium in conjunction with cod-liver oil, for I consider that deficiency in lime salts is a marked feature in the natives of some parts of this territory. I have not found that opium has the specific effect on the phagedænic process that is claimed for it. Nor does iodide of potash seem to make any considerable difference.

Local Treatments.—A multitude of lotions and ointments have been used by numerous people. The object of all is the same—viz., to stimulate the callous and slowly healing tissues to greater activity and more rapid healing. The most popular in the textbooks is 1/1000 perchloride of mercury lotion followed by 5–20 per cent. protargol ointment or 8 per cent. scarlet-red ointment. In the Congo Belge good results are claimed for a powder containing iodoform 2 parts, calcium chloride 20 parts, sodium bicarbonate 78 parts. I have not found this remarkably successful, though it has occasionally been useful. Wet eusol dressings, saline, zinc sulphate, and other lotions have been used. Of the dyes, I have tried methyl violet, brilliant green, and acriflavine. Here again some measure of success can be claimed but results are not consistent. A powder containing zinc oxide and iodoform is popular, and certainly produces a fair number of good results, but, after trying all the remedies already mentioned, I have no hesitation in saying that easily my best results were obtained by a thorough curettage with the application of "bipp." Following this procedure the ulcer is treated on general surgical principles by eusol or other dressings.

Skin Grafts.—When there is a large area to granulate up, skin grafts are of the greatest value in hastening healing, but two not inconsiderable difficulties have to be met. One is the attitude of the native patient who objects to having a new "chilonda" (i.e., ulcer) made, as he thinks, to obtain the skin for grafting, and the other is the great difficulty in preserving asepsis once the grafting has been done.

Antivirus.—Six cases have been treated ab initio by staphylococcus antivirus which was kindly supplied to me by Glaxo Laboratories for the purpose. Unfortunately my work in the Native Hospital was interrupted at this point, but there is no doubt in my mind of the remarkably good effect the antivirus had in cleaning up an ulcer which had received no other treatment. I am definitely of opinion that this line of treatment is well worth extended trial.

Vaccine Therapy.—Investigations are in progress in Salisbury, Southern Rhodesia, with a view to the production of a specific vaccine. The Director of Veterinary Research informs me that so far no "stock" vaccine has been evolved and, as no facilities exist here for the making of vaccines from swabs, I have been unable to investigate this line of treatment

Strapping.—When the ulcer is clean and healin from the edges, firm strapping with zinc oxid strapping is definitely useful. I have had no oppor tunity of trying elastoplast bandages on these cases But as the question of expense is of paramoun importance, I have abandoned my original scheme o firm strapping of the whole circumference of the lim and now employ a piece of strapping which overlap the healing edge of the ulcer by one inch. I find tha this may safely be left in position for a week. Whe it is removed there is always a certain amount discharge but, provided that the preliminary curetta has been thorough and no necrotic material has bee left behind, it will be found that surprising progre in healing has been made. I think that the adva tage of strapping lies in the fact that the edges of t ulcer are approximated and the delicate epitheli cells are protected from injury.

General.—I have come to the definite conclusi that isolation of these cases in so-called "tropi ulcer wards" is not necessary and, in fact, is to deprecated. I now admit them to the general surgi ward, where their beds may be alongside a "clea hernia or gastro-enterostomy case, and the orderl are trained to exercise the usual care while doi dressings and are told that transference of infecti should never occur. So far I have not had any case infection of a clean wound from a tropical ulcer in t ward. This result is, in a large measure, due to t fact that the sister personally supervises eve dressing; and here I wish to emphasise a point whi I regard as of the utmost importance—namely, th good as African orderlies can be and often are, t best results are only obtained by rigid supervision all their work by the medical officer or sister on du If dressings are left to the orderlies without sup vision I find that a definite increase in the length stay in hospital results.

I regard rest in bed as important in the early sta and allow the patient to walk about only when heal has definitely begun and the ulcer has been strapp

X RAY AND ELECTRICAL THERAPY.

I have searched in vain for any references previous work on the treatment of ulcus tropicum X radiation. The librarian at the Royal Society Medicine has been unable to help me, after a k and careful search. I have therefore based my tre ment on suggestions kindly given me by Dr. J. H. Webster and Dr. A. E. Barclay. Two lines of tre ment have been tried, each in a series of 25 cases.

Method A.—First treatment: 5 H. at 80 k.v. unfilter 23 cm. F.s.d.; 3 m.a. Area irradiated includes a ma of about 1 cm. of skin around ulcer. Ten days late series of five weekly doses of 2 H. at 100 k.v.; 23 F.s.d.; 3 m.a.; 0·5 mm. Al. filter.

Method B.—The only difference lies in the fact that in method I have omitted the first unfiltered dose and gi a series of six doses at seven-day intervals of 2 H. at 100 k 23 cm. F.s.d.; 3 m.a.; 0·5 mm Al.; again including the area irradiated a margin of the skin around the ul

During the course of X ray treatment the ulc were swabbed daily with saline, and plain lint soal but it was not painful. nor was there fluctuation. The knees and ankles were normal. Radiography of the right wrist showed no bony change. The wrist was aspirated and 3 c.cm. of purulent synovial fluid were withdrawn. There was a purulent vulvovaginitis. and vaginal swabs were taken. In both the vaginal smear and the joint fluid gonococci and many pus cells were present. Blood culture was negative.

Both wrist-joints were immobilised, and gonococcal vaccine in doses ranging from 2½ millions to 75 millions were given at weekly intervals. The vulvovaginitis was treated by Protargol packs and daily douching with chloramine T. solution. No further aspiration of the wrist-joint was necessary. But for a temporary increase in swelling of the left wrist on the fourth and fifth days the inflammation in the joints subsided rapidly, so that they were normal in appearance and function in a fortnight. The vaginal discharge ceased. and within three months repeated vaginal smears were negative to gonococci.

We have to thank Mr. E. I. Lloyd and Dr. Nabarro for permission to publish this note.

TWO CASES OF UTERUS DIDELPHYS.

By G. S. WOODMAN, M.B. DURH., F.R.C.S. EDIN.,

SENIOR SURGEON, ROYAL HOSPITAL, BAGDAD; CHIEF SURGICAL SPECIALIST, IRAQ.

THE following are two unusual examples of uterus didelphys :—

CASE 1. *Complete uterus didelphys with double vagina.*—A woman, aged 20, married six years, was admitted to the Royal Hospital. Bagdad, on April 4th, 1931, complaining of sterility. Apart from scanty three-day menses recurring every 20–25 days, there was nothing of note in the history. and she was a well-developed young woman with normal secondary sexual characteristics. Per vaginam. above a small cervix, a shade larger than the tip of my second finger, there was no central body but on either side and apparently attached to it, a small pear-shaped mass, and lateral to these easily palpable ovaries. No visual vaginal examination was made. At operation on May 4th (intrathecal percaine) two mobile "half" uteri. widely separated above were found to be fused just above the cervix. Each was about 2½ in. long and had in the normal site a patent tube and normal ovary. A slice was removed from the medial surface of each down to a point where both cavities met and the remaining musculature of each half sutured together without difficulty or tension. Ten days later a probe introduced into the cervix readily reached the new fundus. On withdrawing the speculum. I noticed an aperture. ¼ in. in diameter. to the right of the vagina. Digital exploration demonstrated that this was the narrowed ostium of a right-sided vagina. of considerably smaller bore than the left. from which it was separated by a stout septum the upper end of which intervened between two cervices. both completely circular. Probes passed into each met in the middle line immediately above them.

It is evident that the paring of the two halves prior to their suture was not carried low enough to disclose the presence of the right-sided cervix. which had not. but should have been discovered before operation.

CASE 2. *Removal of the left half of a uterus didelphys seven months after labour in the right half.*—A patient, aged 30, was admitted to the Royal Hospital. Bagdad. on Nov. 17th, 1931. complaining of pain in the left hypogastrium of seven months' duration. Married 13 years. her first pregnancy had terminated seven months before admission. in the birth at the eighth month of a girl who died on the twelfth day. A stormy puerperium. with fever. left-sided pain and vaginal discharge had kept her in bed for three months. For the ensuing four months she had had severe attacks of fever with increased pain. but no discharge. Her periods both before and after pregnancy were irregular. coming on every 10–15 days and lasting 4–6 days. Abdominal examination showed only marked tenderness in the left hypogastrium. Bimanually the cervix was normal in size and position, the uterus large with marked deviation to the right, and the right ovary palpable. On the left side there was a hard tender mass about the size of a tangerine orange.

The abdomen was opened under intrathecal percaine on Nov. 21st. To the large uterus lying well to the right side was attached at the normal site a healthy right ovary and patent tube. There was no evidence of a left tube or ovary. Low down on the left a somewhat pear-shaped mass. its upper end firmly bound to the rectum and Douglas's pouch by dense adhesions and its lower end apparently fixed to the upper part of the cervix was dissected out as far as its neck, on division of which a thick. chocolate-coloured. slightly foul-smelling fluid escaped from small openings in both cut surfaces. The remaining lower portion of the mass was densely adherent in its upper part to the cervix medially and in the base of its inferior expanded portion to the vaginal wall. On removal it consisted of a smooth thick-walled sac—the walls being twice as thick where they enclosed a small opening superiorly. It contained a similar fluid. On superimposition and section of the two parts of the mass, it was seen to comprise a uterus and cervix measuring 2½ in. and a vagina 1¼ in. long. Dissection on its left side revealed an ovary and tube densely matted to the uterus and to each other. The patient made a normal recovery and was discharged on Dec. 6th.

It is difficult to reconstruct the sequence of events in Case 2 which undoubtedly represents a condition of uterus didelphys. It seems more reasonable to suppose from the presence of the pent-up menstrual fluid that the puerperal inflammatory attack had resulted in the closure of a previously existing intervaginal orifice, of which there was no trace in the right vagina, than that the menses had regularly escaped into the abdomen till the tube was closed by the inflammatory process. Whatever the explanation it is remarkable that the right uterus and its appendages suffered so little from the inflammation as compared with the left, presumably due to better natural drainage.

It may be of interest to record that apart from the patient in Case 2, who was a Muslim, all my patients with gross malformation of uterus and vagina have been Nestorian Christians (Assyrians). The latest is that of a case of uterus bicornis whose abdomen I explored on August 10th, 1931, suspecting an ectopic gestation. I found, instead, a pregnancy in the right horn and on Dec. 4th she was delivered of female twins. The explanation of the greater incidence amongst Christians is, I think, to be found in their greater willingness to submit to examination and not to any degeneracy of the Assyrians who, although since 1917 they can hardly be described as a tribal community, are a strong virile race with no signs of excessive interbreeding.

I wish to thank the Inspector-General of Health Services in Iraq for permission to publish this note.

LYMINGTON COTTAGE HOSPITAL.—Extensions and improvements of this hospital have just been completed. A new wing has been added containing six private wards and the necessary accompaniments. and. with money left by the late Mr. Barklie Henry and given by his family, an operating theatre. X ray and massage departments have been provided.

NORTH STAFFORDSHIRE RADIUM CENTRE.—The North Staffordshire Royal Infirmary has been recognised as a regional radium centre, with the use of £5000 worth of radium. A deficit of £947 on the year's working of the hospital brings up the accumulated deficit to £9684. The total cost of each in-patient last year was £9 12*s.* 7*d.*, a decrease of £1 3*s.* 0½*d.*, and the average cost per head per day was 9*s.* 5*d.*, a decrease of 8½*d.* In-patients numbered 5445. a decrease of 203. owing to the temporary closing of several wards for modernisation and redecoration. Out-patients numbered 27,206. a large decrease. At £53,654 the ordinary income fell by £3938; the extraordinary income (mainly legacies) fell by over £5000 to a little over £4000.

CLINICAL AND LABORATORY NOTES

A CASE OF RECURRING SPONTANEOUS PNEUMOTHORAX

WITH ACUTE PRESSURE SYMPTOMS.

By H. Selby, M.B., B.S.Lond.,
MEDICAL SUPERINTENDENT, CREATON SANATORIUM, NORTHAMPTON.

In spontaneous pneumothorax due to tuberculosis the air gains entrance to the pleural space through a breach in the visceral pleura following the breaking down of a subpleural focus. The rupture may be small and rapidly closed by the resultant retraction of the lung; or large and remain patent; or it may be valvular. In the first case, intrathoracic pressure will be little changed; in the second, free communication will exist between the air in the bronchi and that in the pleura so that pressure will be atmospheric and the degree of collapse variable; in the third case, an increasing positive pressure will result with maximal collapse and its results. Introduction into the pleura of contaminated air and products of the causative disease is usually followed by the formation of fluid or pus. If distress is severe, relief is obtained by inserting a needle through the chest wall and allowing some of the air to escape. The following case showed a combination of unusual features.

A. B., aged 21. No family history of tuberculosis. Complained of cough and lassitude 18 months previously, but continued at work until very slight hæmoptysis occurred six months ago when the sputum was examined and found to contain tubercle bacilli. He was ordered to stay in bed, and shortly afterwards developed a spontaneous left pneumothorax with apparent complete collapse of the lung and great displacement of the heart. He remained in bed for six months, and was admitted into this sanatorium on June 18th, 1930. On admission his condition was moderate, temperature 97°–99° F., pulse-rate 90–110, signs of active tuberculosis in both lungs, left lung fully re-expanded, heart normal in position.

On July 29th, 1930, he suddenly became collapsed, complaining of pain in the left chest and difficulty of breathing. Spontaneous pneumothorax was diagnosed. During that night his condition becoming gradually worse a pneumothorax needle was introduced, a small positive pressure was found, and complete relief was obtained by letting out some air. Next morning the dyspnœa increased and the pulse became feeble; a needle was again inserted, 1400 c.cm. of air being allowed slowly to escape, the final mean pressure being reduced to atmospheric. During the next few hours his condition steadily deteriorated, dyspnœa was urgent, pulse bad, cyanosis considerable, and the impulse of the heart could be felt only in the right axilla. The needle was reintroduced and connected by a tube to a bottle of weak antiseptic at the bedside. On this occasion the pressure was too high to be read on the water manometer. The urgent symptoms soon passed off and the patient remained comfortable, the latter half of each inspiratory act being accompanied by a stream of bubbles into the bottle.

On each subsequent day, tests were made to see whether compensation had been established, by partial or complete clamping of the tube leading from the needle, and eventually while the patient was asleep; but on each occasion, and also on two occasions when the needle became blocked by serum, the attempt resulted in the return of alarming symptoms. On the ninth day partial clamping of the tube could be tolerated with the assistance of narcotics, and on the tenth day the needle was removed, cyanosis still being marked, temperature 100° F., pulse-rate 130–140, respiration 40–48. Re-expansion of the lung was slow, X ray showing complete collapse with the heart still on the right side of the sternum four weeks later, and collapse of the upper half of the lung and some mediastinal displacement eight weeks later.

The history of the first attack of left spontaneous pneumothorax was confirmed by the patient's own doctor, Dr. Mary C. Elliot, who noted complete collapse of the lung with great displacement of the heart. Some adhesions may of course have been present on each occasion and have been ruptured by the high pressure, but no evidence of this was present on the second occasion and none of the usual after-effects occurred. This contrasts with the usual experience in treatment by artificial pneumothorax, so often cut short by the development of obliterative pleurisy, and it would have been expected that during the course of slow re-expansion after the first attack some adhesions would have formed. It may be that repeated punctures, variations in intrapleural pressure, and prolonged collapse of the lung predispose to pleural thickening and subsequent adhesions; cases, however, have been described in which collapse has been obtained several months after an artificial pneumothorax had been allowed to re-expand.

No exudation into the pleural cavity was diagnosed *on the first occasion, and none was formed* on the second occasion in spite of presumably severe contamination from the lung and irritation by the presence of a needle for many days. The rupture through the visceral pleura would appear to have been of a valvular nature in view of the persistently increasing intrapleural pressure, and it is likely that compensation occurred when the rupture became fully patent rather than when it healed or was closed by compression. As usual in a tuberculous pneumothorax there was no precipitating factor causing rise in intrapulmonary pressure on either occasion. Both attacks occurred while the patient was at rest in bed.

SUPPURATIVE GONOCOCCAL ARTHRITIS IN A CHILD.

By James Crooks, M.B. Edin., F.R.C.S. Eng.,
SURGICAL REGISTRAR, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON;

AND

A. Gordon Signy, M.R.C.S. Eng.,
CLINICAL ASSISTANT IN THE VENEREAL DISEASES DEPARTMENT OF THE HOSPITAL.

This case seems worthy of record in view of the rarity of gonococcal suppuration in joints as a complication of vulvo-vaginitis in children. It is the only example of this condition that has been seen in an experience of over 15 years and 250 cases of vulvo-vaginitis, at the Hospital for Sick Children. David Lees[1] also reports that "in 200 cases of vulvo-vaginitis no cases of arthritis had occurred, although some American workers give figures as high as 40–50 per cent."

A girl, aged 4½ years, came to the Hospital complaining of swelling and pain of the right wrist-joint for 10 days. The mother stated that both knees, the left wrist, and the right ankle had been similarly but less severely inflamed during the last three weeks; they had subsided without treatment. For one month there had been a vaginal discharge.

The child looked ill, but the temperature and pulse were normal. The right wrist was red, swollen, hot, and tender, and movement was exquisitely painful. The swelling, which was fluctuant, was most marked on the dorsum of the wrist. The left wrist was slightly swollen, and its movements were limited, pressure was "that pressure due to contraction of the arteries under which the red and white cells of the blood can thrive and function to the best advantage." That defined also the basic pressure; there was additional pressure at each heart-beat, and the two combined to constitute the systolic pressure. An increased basic blood pressure interfered with the oxygen-carrying capacity of the red cells, for it modified their surface tension. On the other hand, such a poison as lead in the blood caused a more powerful contraction of arteries—i.e., it raised the basic pressure. He suggested that in diffuse hyperplastic sclerosis the activity of the endothelial cells represented a struggle on the part of those cells to obtain the supply of oxygen which the raised basic pressure interfered with.

---

[1] Lees, D.: The Lancet, 1931, i., 640.

Dr. F. Parkes Weber expressed his belief that, for practical purposes, there was no essential—i.e., primary—hypertension, any more than there was an essential hypertrophy of the heart. In cases of permanent hypertension with an average systolic pressure up to 200 mm. of mercury he thought the condition almost always represented a conservative compensatory or life-prolonging reaction to some cause, either known or unknown. When one heard of some noted person having lived a very long time in spite of his having a very high blood pressure, which had resisted all attempts to permanently lower it, what had probably happened was that he had lived so long in spite of some condition which had been more or less compensated by his high pressure. Indeed, it might be this continued high pressure which had prolonged his useful life, and had his heart not been able to maintain this pressure he would probably have died in middle age. In such cases he thought everything pointed to the high pressure being secondary and compensatory. Prolonged bodily and mental rest tended to lower the blood pressure temporarily. Apart from renal disease, he thought the cause of hypertension in many cases was the arterio-sclerosis which Dr. Evans years ago claimed to be the anatomical manifestation of hyperpiesia. Often, he thought, permanent hypertension represented a special type of reaction to the stress of life.

THE TOXIC CAUSE.

Dr. H. Batty Shaw said that in his view hyperpiesia was of chemical origin. If one was not content with an occasional reading of blood pressure, but took it each night and morning for weeks and months, it would be found to fall periodically to 60 or 70 mm., and a day or two later return to the former height. That fact was a complete answer to those who still maintained that hyperpiesis was no more or less than a reaction to occlusive disease of arteries or arterioles. If the latter view were correct, why did pressure fall without any direct treatment? Also, having fallen so deeply, why did it return to its former level? To him the answer was clear: that the malady was a biochemical one, and that therefore one would look in vain at the bedside for the ætiology; one must go to the chemist for the solution. The former idea that this sustained high pressure was due to a disorder of the suprarenal gland was now generally regarded as exploded. Dr. Evans stated that arterio-sclerosis was an intermediate product, and that it was responsible for the hypertension, but in laying stress on intimal proliferation of vessels and fatty degeneration he thought that Dr. Evans was asking too much of his theory. The speaker was not aware of toxins being produced by fatty degeneration or other changes in the walls of vessels except those due directly to bacteria there. The white patches and retinitis in association with hyperpiesia he considered were due to rupture of the small vessels there, the bursting having been due not primarily to the hyperpiesis or the toxins, but to the patient having been infected, this infection being responsible for the damaged state of the capillaries.

Sir John Broadbent said that before the distinction was made between hyperpiesis and renal disease it was thought that the sustained high blood pressure was due to deficient elimination of nitrogenous bodies by the kidneys. That idea was done away with because many cases of high pressure had no renal disease. Efforts to find free iodine in the blood of these patients were not successful. He thought most would now agree that the cause was some toxin. Starling, it was true, discovered that anæmia of the vasomotor centre would cause prolonged high blood pressure, but no disease was known in which that centre was specially anæmic. High blood pressure could not continue without increased peripheral resistance; there must be some cause acting on the arterioles as well as on the vasomotor centre. The toxin responsible might not necessarily be a bacterial one. Many people were needlessly frightened by being told they had high blood pressure, and they sought drugs to bring it down; it was far better to put them to bed and keep them on a low diet.

Mr. Eardley Holland said that the gynæcologist was sometimes confronted with women who had hyperpiesis in pregnancy, and were advised to terminate their pregnancy, and, he thought, rightly. Occasionally he had cases which illustrated climacteric causes of high pressure; he did not know why, but variations of blood pressure were very common at the climacteric period. It was a time of failure of hormones. He was interested in the possibility of uterine hæmorrhage occurring in association with high blood pressure. He had long refused to believe that high blood pressure could cause the menstrual periods to increase in duration or in quantity.

Prof. Frederick Langmead said he understood that the importance of the suprarenal glands in this connexion was now considered to be overrated, and that opinion was veering round to the pressor substances, to toxins—derived from it was not clear where. No one with much experience of autopsies could deny that patients dying with high blood pressure and cerebral hæmorrhage or heart failure often showed considerable hyperplasia of the suprarenal bodies. Where should this factor be placed in the ætiology?

Dr. Izod Bennett thought that not all renal consequences could be ruled out in a discussion of this sort. Renal ischæmia must be included as one of the three great menaces to life caused by hypertension. Much instruction could be drawn from the group of cases in South Australia, where there were many cases of chronic hypertension and renal failure in young persons, which had been traced to lead poisoning. Dr. Bennett alluded to the value of venesection in hyperpiesia.

Dr. H. Letheby Tidy said that in every case where a patient was known to have died of permanent essential hypertension a change in the nature of an intimal hypertrophy had been found—that change which Dr. Evans described as diffuse hyperplastic sclerosis. After studying the history of the famous Bristol family one could not doubt the hereditary nature of prolonged high blood pressure associated with intimal hypertrophy. Sydenham

MEDICAL SOCIETIES

MEDICAL SOCIETY OF LONDON.

A MEETING of this society on Jan. 25th, with Mr. HERBERT TILLEY, the President, in the chair, was devoted to a discussion on the causation and treatment of

Essential Hypertension.

Dr. GEOFFREY EVANS said that despite many debates the subject was still controversial and indefinite. The term "essential hypertension" was differently used by different people, and he intended to limit it to a condition in which the blood pressure was 170 mm. Hg systolic, or more, and 90 mm. diastolic, or more, over a period of several days at least, with the patient at rest. In these cases there was often some evidence of hypertrophy of the left ventricle and an accentuation of the aortic second sound, which was not obvious in transitory or paroxysmal hypertension arising from emotion, fatigue, or other cause. Cases of persistent hypertension due to renal disease must of course be ruled out from the "essential" group, and also cases in which the rise of blood pressure was symptomatic—whether of retroperitoneal tumour, alcoholic excess, lead poisoning, circulatory failure, infection, or endocrine disturbance.

In essential hypertension there was often a hereditary factor. Thus one patient whose condition was diagnosed at the age of 12 as arterio-sclerosis, and who subsequently avoided over-fatigue, alcohol, and tobacco had a blood pressure of 176/116 at the age of 50. On inquiry it was found that his father died of organic heart disease at 60, his father's two parents of cerebral hæmorrhage when a little over 70, his two sisters of cerebral hæmorrhage at 48 and 60. The patient's mother was alive and well, but her mother died of organic morbus cordis. A striking characteristic of people with essential hypertension was their heavy build, with short thick neck, the females being more of the acromegalic type; the connexion between a heavy build, and obesity, diabetes, and persistent hypertension was well recognised. Some insurance statistics made out that half the cases of hypertension were persons over average weight, and the causes of their deaths were apoplexy, heart disease, and nephritis, in that order. The effect of treatment confirmed this observation, for in some cases reduction of weight was accompanied by reduction of blood pressure. T. S. P. Strangeways had believed that gout was associated with hyperpiesia—a condition from which nephritis was excluded —and had pointed out the association of osteoarthritis with arterio-sclerosis. Dr. Evans did not know whether these were ætiological factors, but perhaps things responsible for one condition might also be held responsible for the other.

FUNCTIONAL AND STRUCTURAL PATHOLOGY.

The profession was still left in doubt about the nature and causation of essential hypertension. One could approach the pathology from two points of view—that of function and that of structure. Functionally it was due to increased resistance in the peripheral systemic circulation. The hypertension was maintained by increased activity of the heart and of the vessels which had to maintain the higher tension. With this increased tension, the reservoir part of the arterial system—the aorta and the largest of the arteries—was stretched, and this stretching resulted in a loss of elasticity, so that pressure was further increased; hence, necessarily, the systolic pressure must increase out of proportion to the diastolic. What determined this persistent hypertension? Was it disturbance of central or peripheral control? Harvey, Cushing, and Starling had shown that anæmia of the bulbar centre caused hypertension, an outflow of vaso-constrictor impulses, in particular to the arterioles, and a rise in systemic pressure. Dr. Evans had looked for an explanation of bulbar anæmia in terms of disease of small vessels supplying the medulla, but without success. There might be chemical changes not yet recognised; or there might be simply an inherited instability of the vasomotor centre; or possibly toxins acted on it.

Could any help be obtained from the morbid anatomy? There was, first, a physiological response to over-function—i.e., proliferation of the media and some thickening of the intima of the vessels. There was also fatty degeneration and obliteration of lumen in the arterioles, and the same in the parent vessels, but without fatty degeneration; and the latter change occurred in some organs only. It took place in the spleen and kidneys to a great extent, also in the suprarenals, the medulla, the pancreas, and to a less extent in stomach and intestines, not in the heart or skeletal muscles. He imagined there was a pathological agent producing both structural and functional change. The nature of this change might throw light on its cause. He did not agree that it was due to arterial hypertrophy. The condition existing had been termed a diffuse hyperplastic sclerosis or arteriolo-sclerosis, which was better than the term arterio-capillary fibrosis, for the change was not fibrotic but proliferative. The lesion might be inflammatory, but if so, one should be looking for chemical toxins rather than emotional strain as a cause. Anderson and Keith had shown that in persistent hypertension there was a thickening of the internal elastic lamina and proliferation of the lining endothelial cells, sometimes accompanied by proliferation of the sub-endothelial tissues, and these changes pointed to some chemical stimulus causing inflammatory reaction.

There was no special treatment for hypertension, and many a person had hypertension without suffering from it; in this respect it was like the fibrosis resulting from healed tubercle. It was necessary to discover whether the hypertension in the particular patient was a symptom of active disease, and whether he was actually suffering from his high tension. If so, it was he who needed treatment and not the hypertension.

Dr. G. ARBOUR STEPHENS said that blood-pressure readings were seldom taken in children, but in view of Dr. Evans's differentiation he thought it would be necessary in future to take the blood pressure of patients of all ages, so as to be able to say whether a rise was temporary or permanent, and how long it persisted in various forms of disease. The pressure depended on the quantity of the blood, its quality, the degree of contraction of the arteries, and the force of the ventricular contraction. The purpose of the circulation was to convey oxygen from the lungs, in which the oxygen tension was about 100 mm. Hg to the tissues, where it was only 20 to 40 mm. This transfer could only be effected if the blood was under suitable pressure. His own description of normal blood n this respect. In hot climates the terrestrial radiation was a great factor, and the amount of heat falling on a body there was double that due to the sun alone. And the atmosphere was responsible for a considerable amount of radiation, because of the contained aqueous vapour. Dry oxygen and nitrogen mixed would have no effect. Emanations of terrestrial radiation were absorbed independently of colour. There was considerable chemical action in short wavelengths and every series had a different effect. Because of the layer of ozone in the upper atmosphere there was very little ultra-violet light in solar radiation.

Atmospheric electricity was invoked to explain almost all the unknowns on this subject. If electricity was going to have any effect on the body it could only be through the electrical field, or free electricity, or through radio-activity. There was always a big electrical field in the atmosphere, so big, indeed, that the difference in potential between the head and the feet when walking in the street was 300 volts, a power sufficient to light a lamp. In a thunderstorm one was subjected to an electrical field of something like 100,000 volts between the head and the toes. There was no physiological effect, however, because we were surrounded by an almost perfect non-conductor, the air. The only exception was when rupture occurred in lightning. We were surrounded by a certain amount of free electricity in the form of electrically charged molecules; it had been computed, however, that there was only one charged molecule in a thousand million million neutral molecules.

Dr. Simpson said in conclusion that he had measured radio-activity in all parts of the world, and he found it so infinitesimal that it could have no effect on health.

DISCUSSION.

Dr. J. KINGSTON BARTON exhibited a graph, showing thermometric and barometric variations during December and the first week in January, and simultaneous variations in death-rates from cerebral hæmorrhage, respiratory diseases other than tuberculosis, and old age. With moderate exceptions there was a coincident rise in the death-rate of all these conditions during the period of abnormal temperature for the season of the year.

Dr. R. KING BROWN said he believed that more iodine was obtained by dwellers at the seaside than those inland, probably because of the decomposition of seaweed. Certainly goitre was uncommon in seaside dwellers. In the view of Sir Leonard Hill, the katathermometer showed the bracing quality of seaside air, but his researches had not yet found their due place in the books. He found that in Victoria (Australia) because of the dryness of the air and the amount of wind, high temperatures could be endured without discomfort.

Dr. C. W. BUCKLEY said he had noted for a long time that cases of rheumatic fibrositis, even those kept in bed or in close stuffy rooms, were very much worse while high winds prevailed, especially (at Buxton) winds from the north-west. They were also in a poor condition just before rain, but much better during rain. Often empiricism came by its own in the long run.

Dr. H. S. STANNUS declared that in the tropics he was able to feel when a thunderstorm was approaching. In the ordinary course he felt very active and could walk many miles, but when a storm was approaching he felt listless and unwilling to do anything.

Dr. W. CRAMER remarked that one of the trying features of the weather in this country was the climatic change from day to day. Climatic conditions stimulated the sympathetic system, the system particularly concerned with heat-regulation and the thyroid and adrenal glands. The results of these influences would naturally be manifested psychologically; in fever the sympathetic system was a defensive mechanism.

Dr. SIMPSON replied.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

ON Jan. 21st at the first meeting of this society to be held in its new premises, Manson House, 26, Portland-place, Dr. C. M. WENYON gave an address on the

Transmission of Leishmaniasis.

He pointed out that since the announcement of Knowles, Napier and Smith in 1924 that the parasite of Indian kala-azar underwent a definite development in the sand-fly *Phlebotomus argentipes* intensive researches had been carried out in India, North China, Sicily, and other places with the object of obtaining evidence that these insects are responsible for the spread of the disease. Similarly since the brothers Sergent, Parrot, Donatien and Béguet, in 1921, had produced oriental sore in man by inoculation of the skin with an emulsion of sand-flies collected at Biskra in Algeria, and Adler and Theodor in 1925 had obtained a like result in Palestine when they inoculated into the skin of a human volunteer flagellates which they had discovered in a *P. papatasii* caught in Jericho, investigations had been concerned very largely with this sand-fly and allied species. In spite of all these investigations, Dr. Wenyon said, in only two or three instances is there evidence that kala-azar and oriental sore have been transmitted experimentally by the bite of a sand-fly. This relative failure has tended towards a revival of older theories and the introduction of new ones, but none of these satisfies requirements.

Leonard Rogers, in 1904, proved that the Leishman-Donovan body was a flagellate of the leptomonas type, and as organisms of this nature are essentially parasites of insects and some other invertebrates and never occur in the free-living condition any theory of transmission of leishmaniasis must take into account the flagellate stage. The Leishman-Donovan body will develop into a leptomonas only in blood media. It will not survive in water or other blood-free fluids, it cannot withstand drying, and quickly dies except in blood media in a culture tube or in the intestine of blood-sucking insects. A typical leptomonas is that of the flea, which lives in the hind-gut and passes from flea to flea directly by means of rounded leishmania forms voided in the flea's dejecta. Such a leptomonas in its natural host displays three important features. First the ingestion by the insect of very few rounded forms leads to heavy infections; secondly, the flagellates attach themselves to the intestinal wall; and thirdly, the infection once established persists for the remainder of the life of the host. Though it has been demonstrated that Leishman-Donovan bodies may escape in the fæces of kala-azar cases suffering from dysentery and even in the urine, that monkeys and other animals may be infected by feeding them with infected tissues, and that occasionally healthy animals will contract infection when kept for months in had declared that to him all manifestations of disease, however harmful, were evidences of a protective reaction on the part of the organism. At present it was impossible to say which came first, intimal hypertrophy or hypertension. When the condition became advanced there was always arteriolo-sclerosis present.

Dr. BERNARD SCHLESINGER referred to a group of cases which had a periodic syndrome consisting of migraine, cyclical vomiting, vaso-vagal attacks, and vertigo. In a number of these cases there was a definite hyperpiesia. But, in contrast to the cases under discussion, in remedying the syndrome the blood pressure tended to fall. The idea was that they had some peripheral vasomotor contraction, and hyperpiesia existed as a temporary compensating phenomenon.

ROYAL SOCIETY OF MEDICINE.

SECTION OF PHYSICAL MEDICINE.

AT the first meeting of this newly constituted section, held on Jan. 15th, with Dr. F. G. THOMSON, the President, in the chair, a paper on the

Meteorological Factors which may Affect Health
